HEALTH EFFECTS OF DIESEL EXHAUST AIR POLLUTION

August 28, 2003

Document prepared by the Environmental Subcommittee/Air Quality Group to be forwarded to the Board of Harbor Commissioners (BOHC) via PCAC

Subject: Committees Findings Regarding Health Effects of Diesel Exhaust Air Pollution; with Concern for Port Activity Related Sources

BACKGROUND: Since its inception the Environmental Subcommittee has been considering the issue of the multiple health effects that have been associated with diesel exhaust air pollution. Experts hired by the Committee, including Professor Avol, Mr. Howekamp, and experts from ARB and AQMD have frequently provided input. These experts also found data for the committee's review from sources they had available. Dr. John G. Miller, an Environmental Sub-committee member and PCAC member cited and provided multiple references from the medical, epidemiologic and scientific literature on this topic. Members of the public have expressed concerns at many committee meetings.

The committee has learned that the Health Risk Assessment Study (HRA) to be completed by consultants hired by the POLA, as one of the Seven Studies mandated by the BOHC, is not scheduled to begin until possibly January 2004, depending on when the (as yet incomplete) Air Emissions Inventory is finished. The completion date for the HRA is currently estimated to be late 2004/early 2005.

Environmental Sub-committee members have heard extensive input from the public requesting no further delay in conveying what it has found to date to the BOHC. This input came both at meetings and in the community. The committee finds no reason for further delay in revealing its findings to date.

The committee notes that Port-related activities, including those that occur off Port property but as a result of Port operations, have been identified by the South Coast AQMD as the largest single unregulated contributor to area-wide air pollution.

Port operations (shipping, loading/unloading, and transport of product) require the use of significant amounts of fuel. Currently most of the trucking, locomotive, and off-road yard operations in and supporting the Port use diesel fuel. The combustion of diesel fuel creates high concentrations of very small particles (numerically, over 90% are less than 1 micron in diameter) and nitrogen oxides. Regional air studies have demonstrated that Port-related emissions are transported widely in the air across the South Coast Air Basin, from the harbor area to Riverside/San Bernardino and beyond. These pollutants have been associated directly (through direct exposure by breathing these pollutants from the air) and indirectly (through participation in photochemical reactions in the air, and breathing the products of these reactions, such as ozone) with a number of health effects.

The Sub-committee has learned that some of these health effects occur even when concentrations of particulates are just one quarter of the Federal limit for outdoor air.

Summary of Health Effects that have been related to Diesel Exhaust Air Pollution as identified and brought to the committee's attention:

1. Prenatal and Perinatal effects
    A. Intrauterine growth retardation
    B. Elevated incidence of low birth weight infants
    C. Increased incidence of spontaneous miscarriage
    D. Increased incidence of respiratory cause of deaths in newborns
    E. Elevated incidence of serious birth defects
    F. Increases in sudden infant death syndrome (SIDS)

2. Childhood effects
    A. Diminished lung growth in children (with unknown long term effects on the individual)
    B. Development of asthma in children involved in active sports
    C. Exacerbations of existing asthma
    D. Elevation of incidence of asthma in children and teenagers. (an ongoing worldwide phenomenon)
    E. Increases in incidence of bronchitic symptoms
    F. Loss of days from school attendance due to respiratory symptoms
    G. Potentiation (enhancement) of allergic effects of known allergens such as ragweed pollen when individual is exposed to diesel particles and the allergen concomitantly.

3. Adulthood
    A. Elevated incidence of lung cancer in a linear relationship with progressive increases in fine particle (Pm 2.5) air pollution (The category Pm 2.5 includes the particles less than 1 micron in size.)
    B. Elevated incidence of myocardial infarctions (heart attacks)
    C. Elevated incidence of mortality from cardiovascular causes (heart attacks and strokes)
    D Triggering of myocardial infarctions associated with spikes in Pm 2.5
    E Elevation of cardiopulmonary deaths in a linear relationship with increases in Pm 2.5
    F. Significant elevations in "all cause mortality" associated with increases in Pm2.5
    G. Increased incidence of bronchitic symptoms
    H. Chronic obstructive pulmonary disease (COPD): increased incidence, prevalence, and exacerbations of existing disease.
    I. Fatal exacerbations of COPD
    J. Exacerbations of asthma leading to time off work, emergency room visits and hospitalizations

K. Approximately 1.5 times elevation in the smoking adjusted incidence of lung cancer in workers occupationally exposed to diesel exhaust versus the smoking adjusted relative risk baseline incidence of lung cancer in similar non-exposed populations.
L. Chronic exposure to particulate pollution shortens lives by one to three years
M. Higher concentrations of particulate air pollution has been linked to low heart rate variability, a risk factor for heart attacks. Association is stronger for people with pre-existing cardiovascular conditions.
N. Mitochondrial damage in cells. (All age groups)
O. Airway inflammatory changes (all age groups)
P. Damage to and death of alveolar and airway macrophages,(all age groups)

This is a brief overview of an extensive and growing body of knowledge. These findings were developed through many avenues of research including but not limited to: epidemiologic studies, clinical studies-retrospective and prospective, autopsy studies, animal studies, cellular biology studies, and Government agency investigations. There has been worldwide scientific participation in research on the links between diesel exhaust air pollution and human health.

This body of knowledge is constantly evolving, with many new pieces of information having been published or brought to light since the inception of Environmental Committee Subcommittee/Air Quality Group. The committee notes that as this an evolving body of knowledge, in many areas further studies are needed.

The Committee finds sufficient evidence to warrant immediate aggressive action by POLA and its tenants to reduce the measurable levels of local and Air Basin wide diesel exhaust air pollution due to Port related activities.

Richard Havenick
Chairman, Air Quality Group

ABSTRACT

Unemployment rates in the United States remain near a 25-year high and global unemployment is rising. Previous studies have shown that unemployed persons have an increased risk of death, but the magnitude of the risk and moderating factors have not been explored. The study is a random effects meta-analysis and meta-regression designed to assess the association between unemployment and all-cause mortality among working-age persons. We extracted 235 mortality risk estimates from 42 studies, providing data on more than 20 million persons. The mean hazard ratio (HR) for mortality was 1.63 among HRs adjusted for age and additional covariates. The mean effect was higher for men than for women. Unemployment was associated with an increased mortality risk for those in their early and middle careers, but less for those in their late career. The risk of death was highest during the first 10 years of follow-up, but decreased subsequently. The mean HR was 24% lower among the subset of studies controlling for health-related behaviors. Public health initiatives could target unemployed persons for more aggressive cardiovascular screening and interventions aimed at reducing risk-taking behaviors.

According to the United States Department of Labor, the US unemployment rate was 9.6% in August 2010 (compared to 5.8% in July 2008), remaining near its highest level in 25 years (United States Department of Labor, 2010). As of July 2010, the unemployment rate was 7.1% in Canada, 5.3% in Australia, 4.9% in Japan, 9.6% in France, 7.3% in Germany, 8.5% in Italy, 4.4% (June 2010) in the Netherlands, 8.4% in Sweden, and 7.8% (May 2010) in the United Kingdom (U.S. Bureau of Labor Statistics, 2010). Even before the 2008–2009 economic crisis, the United Nations International Labor Organization estimated that unemployment had reached a historical high in 2006 (United Nations News Centre, 2007). The *London Times* estimated that, as a result of the current economic crisis, the number of unemployed worldwide could climb further, from 179 million in 2007 to 230 million (Mortished, 2009). This recent rise makes understanding the health effects of unemployment particularly important.

Over the last 4 decades the study of unemployment and its association with health and mortality has expanded significantly (see Hanisch, 1999 for an early comprehensive review on unemployment research). Whether unemployment is causally related to mortality remains an open question (Janlert, 1997; Lundin, Lundberg, Hallsten, Ottoson, & Hemmingsson, 2010; Martikainen, 1990; Martikainen, Maki, & Jantti, 2007; Moser, Goldblatt, Fox, & Jones, 1987), and recent research has begun to focus on possible confounding, mediating, and moderating factors.

One important line of research has been exploring the role of health behaviors such as smoking and alcohol consumption on unemployment and health. This research has generated two major hypotheses regarding the relationship between unemployment and health behaviors. The first, the "coping hypothesis", argues that unemployment causes adverse changes in health behaviors, which in turn lead to deterioration of health (e.g. Hammarstrom, 1994). The second, a "latent sickness hypothesis", suggests that the unemployment-mortality association is spurious because pre-existing health behaviors lead to both unemployment and adverse health (e.g. Jusot, Khlat, Rochereau, & Sermet, 2008).

A second important line of research explores the role of macro-level economic factors in the unemployment-health relationship. National welfare and unemployment policies are thought to play a moderating role, with the negative effects of unemployment being substantially reduced in nations with more generous financial support systems (Bambra & Eikemo, 2009; Gerdtham & Ruhm, 2006;

Jantti, Martikainen, & Valkonen, 2000; Stuckler, Basu, Suhrcke, Coutts, & McKee, 2009). In addition, some researchers have focused on regional and national unemployment rates as a moderator, finding harsher personal unemployment effects when there are relatively few others who are also unemployed (Gerdtham & Johannesson, 2005; Martikainen et al., 2007; Martikainen & Valkonen, 1996; Novo, Hammarstrom, & Janlert, 2001). Others have reported a seemingly paradoxical relationship, noting that dangerous health behaviors decline when the unemployment rate is high (e.g. Ruhm, 2000).

Despite its extensiveness, only one systematic review of the unemployment literature has been conducted (see Jin, Shah, & Svoboda, 1995). This review, however, was qualitative in nature and examined multiple health outcomes. A systematic, quantitative review of the association between unemployment and mortality, arguably the most important outcome, has not yet been conducted. While most studies found that unemployment is associated with decreased longevity, there is no consensus on the magnitude of the association for any sub-group population, and reported relative risks range from 0.68 to 4.83. Furthermore, there is little consensus with respect to which of the possible mediating, moderating, and confounding variables matter most. Meta-analysis is well suited to address this important research problem. Ample cross-study variability now exists to analyze sub-groups and to assess the effects of potential confounding, mediating, and moderating variables.

Mediating and confounding health factors in unemployment research

Early work on the association between unemployment and mortality suggested that the relationship is causal (Moser et al., 1987). More recent work, however, has called this into question and the issue of causation remains unsettled (Martikainen, 1990; Martikainen et al., 2007). Many studies, for example, have documented that persons with pre-existing health conditions are more likely to become and remain unemployed (Bartley & Owen, 1996; Bockerman & Ilmakunnas, 2009; Claussen, 1993; Salm, 2009). Browning, Moller-Dano, and Heinesen (2006) also reported that unemployment did not lead to hospitalization for stress-related diseases. While it has also been found that persons with health problems fare better in the long-run if they maintain or regain employment (Bartley, Sacker, & Clarke, 2004; Huber, Lechner, & Wunsch, 2010), this body of work suggests that pre-existing health may be a common cause of both unemployment and mortality.

Yet many studies continue to find an association between unemployment and mortality even after controlling for pre-existing health status. Whether these provide evidence of a causal link is still uncertain, and much of the debate over causation vs. spurious association has focused on health behavior variables. Unfortunately, the vast majority of individual-level studies of unemployment and health behaviors is cross-sectional and cannot be used to adjudicate between these two hypotheses. Furthermore, many of the macro-level studies of unemployment rates and aggregate health behavior measures cannot be used as they lack individual-level data on health behaviors, health outcomes, and employment status (Catalano & Bellows, 2005). We therefore focus the review below on studies with individual-level data.

The latent sickness hypothesis

Many researchers continue to argue that the unemployment-mortality association is spurious. These scholars argue that health selection into unemployment operates through health behavior variables rather than in a direct manner (i.e. the “latent sickness hypothesis”) (Jusot et al., 2008). For example, if the health problems associated with high levels of drug, alcohol, and tobacco consumption manifest themselves only after the onset of unemployment, controlling for pre-existing health status would not effectively rule out health selection. In support of this view, studies have shown repeatedly that individuals with higher levels of smoking, drinking, and recreational drug use are more likely to become unemployed (Fergusson & Boden, 2008; Hammer, 1997; Hoffmann, Dufur, & Huang, 2007; Leino-Arjas, Liira, Mutanen, Malmivaara, & Matikainen, 1999; Montgomery, Bartley, Cook, & Wadsworth, 1996; Morris, Cook, & Shaper, 1992).

The latent sickness hypothesis is also supported, indirectly, by evidence that the income reduction associated with unemployment actually leads to positive changes in health behaviors (see Temple et al., 1991). Reduced drinking and smoking have been found among the long term unemployed (Fagan, Shavers, Lawrence, Gibson, & Ponder, 2007; Hammer, 1992; Liira & Leino-Arjas, 1999). Furthermore, improved physical activity levels have been found among the recently unemployed (Jurj et al., 2007; Matoba, Ishitake, & Noguchi, 2003). Other studies have found no change in health behaviors, either positive or negative, resulting from unemployment (Gallo, Bradley, Siegel, & Kasl, 2001; Goel, 2008; Iribarria, Ruiz, Pardo, & San Martin, 2002; Peretti-Watel & Constance, 2009; Rehm & Gmel, 1999; Rodriguez & Chandra, 2006; Virtanen et al., 2008).

The coping hypothesis

Other researchers, however, continue to argue for causation, claiming that health behavior variables actually represent an important mediating mechanism through which unemployment is translated into mortality (i.e. the “coping hypothesis”). According to this view, individuals cope with unemployment stress by changing their consumption patterns in unhealthy ways (Hammarstrom, 1994; Laitinen, Ek, & Sovio, 2002; Viinamaki, Niskanen, & Koskela, 1997), particularly individuals with low socioeconomic status prior to the onset of unemployment (Kendzor et al., 2008) and younger persons (Morrell, Taylor, & Kerr, 1998). Individuals with low social status are thought to be particularly prone to negative coping because they feel that this type of stress-relief is all they have left (Peretti-Watel & Constance, 2009).

A large body of work supports the coping hypothesis. First, multiple studies have found that alcohol consumption and binge drinking rise following unemployment (Claussen, 1999). This is especially true among men (Hammarstrom & Janlert, 2003; Mossakowski, 2008; Virtanen et al., 2008), less educated people (Broman, Hamilton, Hoffmann, & Mavaddat, 1995), young persons (Janlert & Hammarstrom, 1992), and those involuntarily unemployed (Ettner, 1997). Second, unemployed persons, especially young men, are also more likely to increase their level of smoking (Barnes & Smith, 2009; Bolton & Rodriguez, 2009; Falba, Teng, Sindelar, & Gallo, 2005; Hammarstrom & Janlert, 1994, 2003; Montgomery, Cook, Bartley, & Wadsworth, 1998; Reine, Novo, & Hammarstrom, 2004). Unemployed smokers are less likely to attempt smoking cessation (Weden, Astone, & Bishai, 2006) and are more likely to relapse from smoking cessation efforts (Falba et al., 2005). Finally, unemployed persons are more likely to increase their use of illicit drugs (Alegria et al., 2004; Hammer, 1992; Merline, O'Malley, Schulenberg, Bachman, & Johnston, 2004) or begin using drugs (Crofts, Louie, Rosenthal, & Jolley, 1996; Green, Doherty, Reisinger, Chilcoat, & Ensminger, 2010).

Negative health consequences may also arise through the tendency of people to react to unemployment by reducing their personal spending. Research has shown that unemployed persons often substitute poorer quality diets for better ones. This may result in obesity (Laitinen, Power, Ek, Sovio, & Jarvelin, 2002), or in unhealthy weight loss (Bolton & Rodriguez, 2009). Some have even found that the threat of unemployment alone was enough to cause increased body mass index (BMI) (Ferrie, Shipley, Marmot, Stansfeld, & Smith, 1998). Once unemployed, increased BMI creates a feedback loop, as those who are judged as overweight have difficulties in finding work (Johansson, Bockerman, Kiiskinen, & Heliovaara, 2009; Paraponaris, Saliba, & Ventelou, 2005) and increased BMI may therefore lead to permanent labor force withdrawal (Alavinia & Burdorf, 2008).

The present study seeks to assess the impact of potential mediating, moderating, and confounding factors on the association between unemployment status and mortality. First, we evaluate the impact of pre-existing health status and health behaviors, variables that are central to the current debates in the literature. Using meta-analysis, we compare results from studies that controlled for health and/or health behaviors with other studies that did not. Second, in light of the literature on the potential moderating effects of national health care systems, we compare study results between countries with national health care systems and those without. Finally, we assess the potential moderating roles of gender, age, time, follow-up duration, and case/control group composition on the unemployment-mortality association. In each instance, we capitalize on cross-study variability to assess the impact of key factors. Becoming unemployed may also have a mediated effect on health due to the psychosocial stress of being forced into a lower social status (Fineman, 1979; Martikainen & Valkonen, 1996), but this mediating factor is often assumed rather than empirically examined, and is therefore beyond the scope of the present study.

Methods

Search strategy and coding procedures

In June 2005, we conducted a search of electronic bibliographic databases to retrieve all publications combining the concepts of psychosocial stress, including unemployment, and all-cause mortality. We re-ran the electronic keyword searches in these databases in July 2008 and completed the search and coding stages in January 2009. We used 100 search clauses for Medline, 97 for EMBASE, 81 for CINAHL, and 20 for Web of Science. See Section 1 of Appendix for the full search algorithm used for Medline (information on the remaining search algorithms are available from authors upon request). We identified 1570 unique publications. Using these results as a base, we iteratively hand-searched the bibliographies of eligible publications; the lists of sources citing an eligible publication; and the sources identified as “similar to” an eligible publication. Hand-searching was ongoing for three and one-half years and was completed after 8 iterations (the full description of this iterative search protocol is documented and available from the authors upon request).

The electronic database searches were performed by a research librarian. Two authors (DR and ES) trained in systematic review coding procedures (Lipsey & Wilson, 2001; Stock, 1994) determined publication eligibility and extracted the data from the articles, consulting a third author (JS) when required (see Section 2 of Appendix for additional details regarding coding procedures and variables for which data were sought). Any unpublished work encountered was considered for study inclusion. Although our search was done in English, we were able to locate and translate the relevant portions of 35 publications written in German, Danish, French, Spanish, Dutch, Polish, or Japanese. Fig. 1 summarizes the number of publications considered at each step of the search process. The full database contains 262 publications examining the associations between various stressful events and all-cause mortality. To evaluate coding accuracy we randomly selected and recoded 40 of these publications (including 446 point estimates). Of the point estimates, 98.6% were free of coding errors.

The present analysis uses the subset of articles ($n = 42$) that reported the association between unemployment and all-cause mortality. Forty of these publications appeared in peer-reviewed

Abbreviations: HR, hazard ratio; OPCS, Office of Population Censuses and Surveys.
[a] Average HRs were obtained by calculating the unweighted average of all mortality risk estimates for a given study after conversion into HRs.
[b] Denotes a combination of unemployed persons and those not in the labor force.
[c] Original publication in Spanish.
[d] Unpublished dissertation.

journals; 1 in a book chapter; and 1 in an unpublished dissertation. One publication was translated from Spanish in consultation with a native speaker; the remaining 41 publications were in English (Table 1). Other subsets of the database of 262 publications were used to produce analyses of war-related stress (Roelfs, Shor, Davidson, & Schwartz, 2010), widowhood (Roelfs, Shor, Curreli, Clemow, Burg, & Schwartz, in press), marital dissolution (Shor, Roelfs, Bugyi, & Schwartz, unpublished), and other psychosocial stressors.

Statistical methods and inclusion criteria

For the present analyses, a study was included if the outcome variable was all-cause mortality, unemployment was measured at the individual level (rather than at the neighborhood level), and a clear comparison was made between a group of people who experienced unemployment and another group who either did not experience unemployment at all or experienced it to a lesser degree. As shown in Table 1, most studies compared unemployed persons with employed persons, while a few compared unemployed persons with the general population. We examined whether this distinction affected the estimated association between unemployment and mortality.

Statistical methods varied from study to study, necessitating the conversion of odds ratios, rate ratios, standardized mortality ratios, relative risks, and hazard ratios (HRs) into a common metric (See Section 3 of Appendix). For 63 of the 235 measures of mortality risk, the death rate information required for conversion to a common metric was not reported. In these cases, the required death rate was estimated using multiple regression analysis (see Section 4 of Appendix). Sensitivity analyses were performed to examine the possible effect of including or excluding studies for which an estimated death rate was used in the conversion to a common metric.

As is standard practice, we used the standard errors reported in the publications to calculate the inverse variance weights (See Section 5 of Appendix). When not reported, standard errors were calculated using (1) confidence intervals, (2) t statistics, (3) χ^2 statistics, or (4) p-values. When upper-limit p-values were the only estimate of statistical significance available (e.g. in cases where we knew only that the p-value lay somewhere between 0.01 and 0.05), the midpoint of the upper and lower limits was used to estimate the p-value. In 24 cases, no measure of statistical significance was reported and standard errors were estimated using multiple regression (See Section 4 of Appendix). An indicator variable was created so analyses could be conducted both with and without data points where the standard error was estimated.

Quality was assessed using the Newcastle-Ottawa scale for nonrandomized trials (Wells et al., 2009). Two authors (DR and ES) also independently rated each publication, the average from these two ratings being used in the analysis.

Q-tests, I^2 tests, and examinations of the unexplained heterogeneity variance component were used to assess the presence and magnitude of heterogeneity in the data (Huedo-Medina, Sanchez-Meca, & Marin-Martinez, 2006). Q-test results from preliminary analyses revealed substantial heterogeneity across studies' effect sizes. In light of this all meta-analyses and meta-regression analyses were calculated by maximum likelihood using a random effects model and sensitivity analyses were conducted using the variables identified by the meta-regression models as significant sources of heterogeneity. Analysis was performed with statistical software (PASW, version 18.0) using matrix macros provided by Lipsey and Wilson (2001). The possibility of selection and publication bias was examined using a funnel plot of the log HRs against sample size. Funnel plot asymmetry was tested using Egger's test (Egger & Davey-Smith, 1998). Due to the heterogeneity in the data, funnel plot asymmetry was also tested using weighted least squares regressions of the log HRs on the inverse of the sample size (Moreno et al., 2009; Peters, Sutton, Jones, Abrams, & Rushton, 2006).

Analyses performed include meta-analyses of sub-groups, bivariate meta-regression analyses, and multivariate meta-regression analyses. The covariates used in the analyses were dictated by data availability. Variables such as race or ethnicity, which were used as grouping variables or included in interaction terms in only a small number of studies, could not be used in the analyses. Likewise, variables summarizing the prevalence of smoking or drinking, and other health behavior variables that would have been useful for additional analyses of confounding, were not reported and could therefore not be examined. The following independent variables were used in these analyses: (1) whether death rate was estimated (yes or no); (2) whether standard error was estimated (yes or no); (3) proportion of respondents who were male; (4) mean age of sample at baseline; (5) age of the study (i.e. years elapsed since the beginning of baseline), divided by 10; (6) time elapsed between the end of baseline and the beginning of follow-up; (7) maximum follow-up duration; (8) type of comparison group; (9) geographic region; (10) sample size, log transformed; (11) Newcastle-Ottawa Scale rating (range, 0–9); and (12) a series of variables indicating whether sex, age, socioeconomic status, and health were statistically controlled.

Results

Table 1 provides summary information on the 42 publications included in this study. This table is presented in lieu of the standard meta-analysis forest plot because of space limitations and the inherent difficulty in garnering data heterogeneity information from a plot that contains 235 point estimates and confidence intervals. The mean relative risk from each of the 42 publications, however, was included in Table 1 in the interest of providing information from which some heterogeneity observations might be made. The forest plot is available from the authors on request.

Table 2 provides descriptive statistics on the 235 mortality risk estimates included in this study. Data were obtained from 42 studies, published between 1984 and 2008, covering 15 countries (mostly in Europe and North America), and representing more than 20 million persons. The majority of persons analyzed were men, and almost all were of working-age at baseline. The average follow-up duration across all studies was 9.02 years. Of the HRs analyzed, the mean 5-year impact factor was 5.59 and the mean number of citations received per year since publication was 2.68. The mean score on the Newcastle-Ottawa Scale was 7.76.

Table 3 presents the results of a number of meta-analyses (See Table 4 for sample size information). All analyses were stratified by the level of statistical adjustment of the risk estimate. Persons who experienced unemployment were significantly more likely to die than the comparison group. The mean unadjusted HR was 2.08 (95% confidence interval [CI], 1.77–2.43; $n = 40$ risk estimates); age-adjusted HR, 1.59 (95% CI, 1.42–1.77; $n = 75$); and HR adjusted for age and additional covariates, 1.63 (95% CI, 1.49–1.79; $n = 120$). These results show that unemployment is associated with a 63% higher risk of mortality in studies controlling for covariates. Table 3 also shows that the exclusion of data where either the death rate or the standard error had to be estimated does not alter the direction, magnitude, or level of statistical significance of the mean HRs.

sub-group meta-analyses and meta-regression analyses

As described at the end of the methods section, data on the prevalence of high BMI, smoking, drinking, drug use, or other

health factors was not available for analysis. However, comparisons between the subset of our data where health was directly controlled ($n = 45$ HRs) or where health-related behaviors were controlled ($n = 27$ HRs) and the remaining data still provides results relevant to the debate between the coping hypothesis and the latent sickness hypothesis. Table 5 presents the results of the meta-regression analyses, which provide a multivariate test for differences between key sub-groups. Model 1 shows that there was no significant difference in HR magnitude between studies that controlled for any measure of health and the remaining studies ($p = 0.1236$). Model 3, however, shows that the mean HR was 24% lower for studies that controlled for one or more health behaviors, when compared to the remaining studies ($p = 0.0159$). These results suggest that health behaviors may confound the unemployment-mortality association to some degree. However, the results also indicate that pre-existing health behaviors and conditions do not account for 100% of the relationship between unemployment and mortality (see the discussion for more on this issue).

Previous studies suggested that gender is a key moderating variable for the unemployment-mortality association. Preliminary examinations of individual studies revealed qualitative differences between the magnitude of HRs for men and for women, suggesting that women and men be analyzed separately. Table 3 shows that unemployment was associated with an increased risk of death when HRs were adjusted for age and additional covariates. However, gender-specific analyses show that the magnitude of the association was greater for men (HR, 1.78; 95% CI, 1.56–2.02; $n = 54$ HRs) than for women (HR, 1.37; 95% CI, 1.17–1.60; $n = 36$). Model 3 of Table 5 confirms that the proportion of a sample that is male had a significant impact on the magnitude of the HR. The risk of death for men was 37% higher than that for women ($p < 0.001$).

Previous research has also suggested that age may moderate the association between unemployment and mortality. We therefore also conducted sub-group analyses based on average age at baseline. As shown in Table 3, unemployment was associated with a 73% increased risk of all-cause mortality for people under the age of 40 years who were in their early careers (HR, 1.73;95% CI, 1.41–2.11; $n = 29$) and a 77% increased risk for those between the ages of 40 and 50 years who were in mid-career (HR, 1.77; 95% CI, 1.59–1.98; $n = 70$). The association was substantially reduced for those between the ages of 50 and 65 years who were near the end of their working careers (HR, 1.25; 95% CI, 1.03–1.52; $n = 19$). The results of the meta-regression analysis (Model 3 of Table 5) show a significant effect for mean age (a 6% decrease for each additional 10 years; $p = 0.0165$) confirm this finding, with HR magnitude being approximately equal between the youngest and the middle age group ($p = 0.4394$) but 26% lower for the oldest age group ($p = 0.0016$).

While follow-up duration has not often been explored in the literature as a moderating factor, preliminary examinations of individual studies suggested that the association between unemployment and mortality may change as time passes. Sub-group analyses based on follow-up duration (Table 3) show that people who experienced unemployment had a 73% higher risk of death during the first 5 years of follow-up (HR, 1.73; 95% CI, 1.44–2.06; $n = 30$). The elevation of risk of death remained approximately the same when the follow-up duration averaged 5 to 10 years (HR, 1.76; 95% CI, 1.55–2.00; $p < 0.001$; $n = 47$) but then decreased to a 42% elevation of risk in studies with a follow-up of more than 10 years (HR, 1.42; 95% CI, 1.22–1.64; $n = 43$). However, the meta-regression results indicate that there was no significant trend associated with follow-up duration ($p = 0.3476$).

Furthermore, the type of comparison group used may also have an effect on the magnitude of the mean HR. Preliminary comparisons of individual studies confirmed this, leading us to also examine sub-groups results based on the type of comparison group used. The mean HR was much higher when the comparison group was employed persons only (HR, 1.75; 95% CI, 1.54–1.98; Table 3) than when the comparison group was the general population (HR, 1.24; 95% CI, 1.01–1.51). The results of meta-regression analysis (Table 5) confirm this, showing that HRs were 32% lower when the general population was used as the comparison group ($p < 0.001$). Table 3 also shows that the risk of death was marginally lower when studies excluded persons not in the labor force (HR, 1.60; 95% CI, 1.45–1.76) than when studies included a mixture of unemployed persons and those who were not in the labor force (HR, 1.73; 95% CI, 1.46–2.04). However, the meta-regression analyses (Table 5) show that when unemployed persons were combined with persons not in the labor force the HR increased by 46% ($p < 0.001$) once other study-level factors were controlled.

[a] All meta-analyses were calculated by maximum likelihood using a random effects model. See Table 4 for information on sample sizes for each analysis. Values are presented as mean hazard ratio (95% confidence interval). Unless indicated otherwise $p \leq 0.001$. Ellipses indicate situations where $n \leq 1$ and meaningful mean HR could not be calculated.
[b] The number and type of covariates varies between studies.

Sensitivity analysis

The between-groups Cochrane's Q for the meta-analysis of all 235 HRs was statistically significant ($p = 0.0149$) and the I^2 statistic was quite high (I^2, 76.2; 95% CI, 22.1–92.8), indicating that important moderating variables exist and supporting the decisions to use random effects models and conduct sub-group meta-analyses. As shown in Table 4, the *Q*-tests for these sub-group meta-analyses were statistically significant only for statistically-unadjusted HRs. In all of the remaining sub-group analyses however, *Q*-tests and I^2 tests were non-significant, indicating that heterogeneity was adequately accounted for by the use of a random effects model. Since the discussion of the meta-analysis focused on HRs adjusted for age and additional covariates, the results discussed above are not an artifact of heterogeneity in the data.

To be conservative however, meta-regressions were used to examine other possible sources of heterogeneity in the data. The model fit statistics for Model 3 of Table 5 (R^2, 0.3702; $p < 0.001$ for

[a] All meta-regressions were calculated by maximum likelihood using a random effects model. N = 235 hazard ratios for all analyses. Numbers reported are the exponentiated regression coefficients (exponentiated 95% confidence intervals). Ellipses indicate situations when a variable was not entered into a model.
[b] Obtained using backwards elimination, variables removed if $p > 0.10$.

the Cochrane's Q of the model) indicate that this model captured a very substantial portion of the heterogeneity in the data. Nevertheless, the unexplained heterogeneity variance component for this and the other models shown in Table 5 was highly significant (each $p < 0.001$), confirming the need to use a random effects model for all analyses.

As reported earlier, health behaviors, sex, mean age, and the composition of the case and control groups moderate the mean HR. Model 3 of Table 5 shows that other significant moderators include the time elapsed between the end of baseline and the beginning of follow-up (a 6% increase in risk for each additional year; $p = 0.0006$), whether the risk estimate was adjusted for age (a 16% decrease when age was controlled; $p = 0.0159$), and whether the risk estimate was adjusted for socioeconomic status (a 13% decrease when SES was well-controlled; $p = 0.0265$). While HRs from the United States and the Scandinavian nations are over-represented in the data, the results do not seem to be biased by this factor as there was no significant difference in HR magnitude between either region and the remaining nations ($p = 0.7707$ and $p = 0.9216$, respectively).

Of the 235 HRs, 93 were statistically-adjusted for age or had an age range smaller or equal to 35 years, did not use the general population as the control group, did not include persons not in the labor force in the case group, were from studies with less than a one year gap between the end of baseline and the beginning of follow-up, and were from studies in which men and women were analyzed separately. These 93 HRs were then grouped according to sex and age group, the resulting six sub-groups subjected separately to meta-analysis (see Table 6). The mean HR among women under the age of 40 was 1.73 (95% CI, 1.41–2.11; *n*, 19), was 1.34 (95% CI, 1.15–1.56; *n*, 14) when the mean age was 40 to 49.9 years, and was 0.94 (95% CI, 0.80–1.11; *n*, 9) when the mean age was 50 years or above. The mean HR among men under the age of 40 was 1.95 (95% CI, 1.69–2.26; *n*, 26), was 1.86 (95% CI, *n*, 14) when mean age was 40 to 49.9 years, and was 1.17 (95% CI, 1.00–1.36; *n*, 11) when the mean age was greater than or equal to 50 years. In all six meta-analyses, the *Q*-test was not significant and the I^2 statistic was not significantly different from zero, indicating homogeneity in the data. The high correspondence between these six more conservative meta-analyses and the full sample meta-analyses reported in Table 3 further confirm that heterogeneity in the sub-group data was not a major problem.

Discussion

Our findings show that unemployment was associated with an increased relative risk of all-cause mortality. We show that the risk of death was 63% higher among those who experienced

Table 6
Meta-analyses stratified by gender and age.[a]

Gender	Mean age	HR (95% CI)	*n*	*Q*-test *p*-value
Women	Less than 40	1.73* (1.41, 2.11)	19	0.937
	40–49.9	1.34* (1.15, 1.56)	14	0.233
	50–65	0.94 (0.80, 1.11)	9	0.999

[a] Analyses based on 93 hazard ratios that were statistically-adjusted for age or had an age range smaller or equal to 35 years, did not use the general population as the control group, did not include persons not in the labor force in the case group, and were from studies with less than a one year gap between the end of baseline and the beginning of follow-up.

unemployment than among those who did not, after adjustment for age and other covariates. Before proceeding to a more detailed discussion of the specific findings, however, some important limitations must be considered.

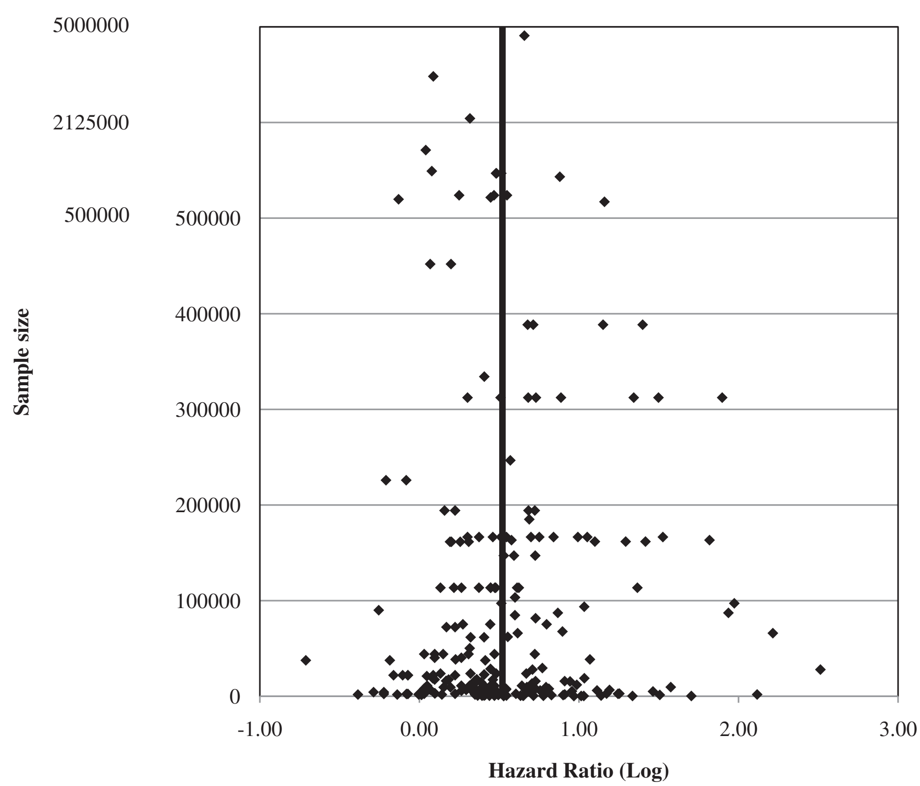
Limitations

There is also an unknown degree of nonreporting of non-significant findings (also known as the file-drawer effect) and selection bias that may affect the results (Berman & Parker, 2002; Egger & Davey-Smith, 1998). For example, some may suggest that the inclusion of studies based on census data is problematic because their analyses often rely on comparisons with the general population, as opposed to the employed population. While this is a valid point, we have tried to control for this by including the appropriate indicator variables in the analysis. To guard against other aspects of selection bias, we excluded no publications containing data on the association between unemployment and mortality. As with all meta-analyses however, some studies of the association between unemployment and mortality will have been missed. The funnel plot of the log HRs against sample size appears asymmetric around the mean HR, suggesting significant selection bias (Fig. 2). The results of Egger's test indicated significant funnel plot asymmetry ($p < 0.001$). However, recent simulation studies indicate that heterogeneity in the data (such as is the case here) produces misleading Egger's test results (Moreno et al., 2009; Peters et al., 2006; Terrin, Schmid, Lau, & Olkin, 2003). Using Peters' test (Moreno et al., 2009; Peters et al., 2006), we regressed the log HRs on the inverse of the sample size. The results of this second test indicated non-significant levels of funnel plot asymmetry after data heterogeneity had been taken into account ($p = 0.993$). Given the discrepancy in the results of the two tests, however, caution is warranted in the interpretation of the results.

Another limitation stems from the reliance on studies with observational designs, which limit the ways in which one can account for potential confounders. None of the studies of unemployment were randomized clinical trials, as unemployment is not a "treatment" one induces. In the worst case scenario, the use of an observational design creates the risk that one or more highly important confounding factors are not accounted for and the results of the study are biased (Egger, Schneider, & Davey-Smith, 1998). Even when important factors are controlled, differences in the method of control between studies have the potential to affect the results of a meta-analysis. For example, Model 3 in Table 5 shows that the method for controlling for socioeconomic status affects the magnitude of the HR. While the HR associated with unemployment is elevated across all levels of control for SES, the mean HR was 13% lower among the subset which measured SES using two or more factors. There is a danger of systematic bias in our results due to our reliance on studies with observational designs and due to the different methods used to control for confounders in the studies we examined. However, this danger is reduced by our efforts to account for the mediating, moderating, and confounding factors that have thus far been investigated in the literature.

Discussion

Three findings from our study support the idea that the pathway between unemployment and mortality is not completely spurious, and could be consistent with a causal association. First,



[a]Vertical line denotes the mean log hazard ratio of 0.52. To better show the dispersion of points, the y-axis scale is less condensed from 0 to 500 000 and more condensed from 500 000 to 5 000 000.

Fig. 2. Funnel plot of logarithmic hazard ratios vs. sample size[a].

unemployment remains associated with an increased risk of death even after the exclusion of individuals who were not in the labor force. This supports Moser et al.'s (1987) finding that elevated risk levels among the unemployed were not simply an artifact of misclassification. Second, the lack of significant difference between the subset of our data where health was directly controlled ($n = 45$ HRs) and the remaining data ($p = 0.1236$) suggests that pre-existing health problems were not, in a broad sense, the common cause of both unemployment and mortality. These findings are consistent with those of Lundin et al. (2010), who reported that a substantial portion of the association between unemployment and mortality remained even after accounting for possible confounding factors. However, our regressions indicated that the 27 HRs that controlled for health behaviors were 24% lower than the remaining HRs ($p = 0.0159$). This latter result provides limited support for the latent sickness hypothesis. Health-related behaviors existing at baseline account for a portion of the unemployment-mortality association and are clearly important to include in future studies. However, the coping hypothesis provides a better overall explanation as the lack of large differences in HR magnitude suggests that the post-unemployment pathway exerts a stronger effect on mortality outcomes. The method available to us for the testing of these competing hypotheses, while suggestive of the overarching patterns, cannot provide definitive evaluations of these hypotheses.

The results of this systematic review confirm our early expectations that the estimated adverse association between unemployment and mortality would not be uniform across all sub-groups and studies. Meaningful differences were observed by age group, gender, follow-up duration, time period, geographic region, and case and control group composition.

First, mean HRs were higher for those in their early and middle careers (an increased risk of 73% and 77%, respectively) but lower for persons in their late careers (only a 25% increase in risk), a finding consistent with those of earlier reports (Iversen, Andersen, Andersen, Christoffersen, & Keiding, 1987; Moser, Fox, & Jones, 1984; Sorlie & Rogot, 1990). This pattern may be the result of a smaller net increase in stress among older workers, who often hold jobs with above average stress levels and who may have already been contemplating retirement (Brenner & Levi, 1987). The pattern may also result from health selection into retirement among older workers (Disney, Emmerson, & Wakefield, 2006), a process that leads to the overrepresentation of healthier older persons in the workforce. Some caution must be exercised when interpreting this finding. When the underlying death rates are very high in both the case and control groups (as is the case at older ages), ratio statistics such as the HR lack statistical power to detect group differences. However, this is not likely a problem in the present study because we focus on the working-age population. The death rates remain low enough to enable ratio-type measures such as HRs to detect differences in death rates between the employed and unemployed.

Second, this study confirms that the magnitude of the association between unemployment and mortality is higher for men than for women (an increased risk of 78% vs. 37%). There are two possible explanations for this finding. First, the labor force participation rate for women is considerably lower than for men in most nations. Being engaged in unpaid labor at home or employed as part-time or on a temporary basis may provide less health protection than full-time work. The data can be used to partially evaluate this first explanation. The difference between men's and women's labor force participation rates is particularly low in the Scandinavian nations, and if this first explanation is valid one would expect to see a correspondingly smaller difference between men's and women's relative mortality risk. To test this we included an interaction term between gender and Scandinavian region in a separate meta-regression (not shown in tables, but using the same covariates as Model 2 in Table 5). The lack of significance for the interaction term ($p = 0.8156$) suggests that absolute differences in the labor force participation rate between men and women do not account for differences in the relative mortality risk. A second explanation for the gender gap in relative mortality risks may be that employment status remains more central to men's identities than to women's *despite* the continuing upward trend in women's participation in the formal labor market. This explanation cannot be evaluated with our data.

Third, the association between unemployment and mortality is significant in both the short and long term. While the meta-analysis results showed a decrease in the mean risk of mortality in those studies where the follow-up period exceeded 10 years (the risk dropped from 76% to 42%), this trend was not significant in the final meta-regression model ($p = 0.3476$). This finding must be approached conservatively as it may result from the fact that many of the studies included in the meta-analysis were cross-sectional. In cross-sectional studies the employment status reported at baseline tends to become less and less accurate as time passes. In other words, group differences may become obscured over time because some of those who initially reported being unemployed later found work and some who were employed at baseline (and served as the comparison group) later lost their jobs. The constancy of the mean relative risk over time, however, does lend some support to the hypothesis and previous findings that both the stress and the negative lifestyle effects associated with the onset of unemployment tend to persist even after a person has regained a job (Bolton & Rodriguez, 2009; Cohen et al., 2007; Janicki-Deverts, Cohen, Matthews, & Cullen, 2008; Khan, Murray, & Barnes, 2002; Montgomery et al., 1998; Wadsworth, Montgomery, & Bartley, 1999).

Fourth, the results of the meta-regression analyses show no significant changes in the magnitude of the unemployment-mortality association over the last four decades, as shown by the lack of a significant association between the age of a study and the magnitude of the HR (Model 2 of Table 5; $p = 0.6972$). Despite dramatic changes in the composition of the workforce and in work environments over this period (such as women's increased labor market participation, changing government unemployment policies, and the general trend towards more part-time and temporary jobs), the association between unemployment and mortality remained unchanged.

Fifth, the results of the meta-regressions suggest that differences between national welfare and health care systems may not translate into differences in the magnitude of the unemployment-mortality association. Ideally, this question would be tested using a direct measure of national health system scope. While this data was not available for our analyses, the geographic region variables can be used to partially assess the hypothesis. Among the nations represented in this study (see Table 2 for a complete list), only the United States lacks some form of universal health coverage. Furthermore, unemployment benefits in the United States tend to be less generous than in most of the other nations examined. In contrast, public health care coverage is most comprehensive in the Scandinavian nations. If the degree of coverage provided by national welfare and health care systems was related to the unemployment-mortality association, one would expect to see significant differences in HR magnitude between the U.S. and the Scandinavian nations. The lack of a significant difference between the mean HR for the U.S. ($p = 0.7707$), Scandinavia ($p = 0.9216$), and the remaining nations suggests that these national-level policy differences may not have much of an effect on the rate of mortality following unemployment. This result should be treated conservatively and should not be extrapolated to populations in developing countries, as almost all the data came from studies of the developed world.

Finally, the composition of both the cases and controls was important. When comparing unemployed persons with the general population, the effect is much smaller than when comparing unemployed persons with employed persons (the risk decreases from 75% to 24%). This is to be expected because the general population, while primarily consisting of employed persons, also includes some unemployed persons and individuals who are not in the labor force (e.g. early retirees, the disabled, homemakers, and students). Furthermore, the mean risk of death increases (from 60% to 73%) when those who are not in the labor force are mixed with the unemployed. This confounds the stress of unemployment with health status and other factors that may influence the magnitude of the association. These findings suggest that future studies of the unemployment-mortality association must strive to include only unemployed persons as cases and only employed persons as controls. The quality of study design is critical for assessing the risk of death among unemployed persons because this risk tends to be understated if cases or controls are not both precisely specified.

Conclusion

This study shows that unemployment was associated with a substantially increased risk of death among broad segments of the population. Future research should continue to focus on possible mediating, moderating, and confounding factors and on whether this risk is modifiable, either at the health system level or the individual level. Until more is known about the mechanisms by which this association occurs, more proactive primary prevention screening and interventions among the unemployed are needed. Due caution is warranted, however, as Dorling (2009) suggests that some interventions, such as low-wage work programs, appear to exacerbate the hazard of dying due to unemployment. However, studies suggest that cardiovascular screening programs among the unemployed, interventions aimed at increasing unemployed persons' awareness of behavioral risk factors (Hanewinkel, Wewel, Stephan, Isensee, & Wiborg, 2006), and stress-management programs (aimed at preventing risk-taking behavior that leads to the observed increase in injury rates among the unemployed) may be particularly beneficial. Studies such as the current one are particularly important in the current economic climate, with many national unemployment rates exceeding 10% and expected to remain elevated for some time. Much work remains to be done using more detailed specifications of unemployment for which systematic data could not be found. Studies should be conducted in developing nations, where welfare and health care systems are much less developed and unemployment may result in more direct threats to a person's health. Future studies should also collect data on unemployment duration, informal labor market participation, sources of support, and other possible mediators beyond those discussed in this paper.

Acknowledgments

The authors are grateful for the support provided by grant HL-76857 from the National Institutes of Health. The funding source had no involvement in the collection, analysis and interpretation of the data, in the writing of the report, and in the decision to submit the paper for publication.

Section 2: Coding procedures and variables for which data were sought.

As already mentioned in the main text, two authors (DR and ES) trained in systematic review coding procedures determined publication eligibility and extracted the data from the articles. Prior to coding, both authors jointly reviewed the titles and abstracts of potential publications to determine whether a given work warranted a full examination for coding purposes. Each of these publications was read independently, with each author forming an opinion on final publication eligibility, assigning a tentative subjective quality rating, and highlighting the data to be coded (see below). The two authors then met in conference to discuss each publication. Data was entered into a spreadsheet only after agreement had been reached on final publication eligibility, the number of relative risk estimates available for extraction, the values to be assigned for the study design variables (e.g. age range, baseline date) corresponding to each relative risk, and consensus had been established with respect to the final subjective quality rating. In some cases, the data entry involved calculating relative risk estimates from raw death rates or from raw count data. For publications reporting multiple analyses of a single sample, data was sought from a statistically-unadjusted model, a model adjusted for age alone, and from the most statistically-adjusted multivariate model. Data was entered basic spreadsheets (the data spreadsheet being later imported into SPSS for analysis). The variables we sought to obtain from publications were:

1) Author names; 2) author genders; 3) publication date; 4) publication title; 5) place of publication; 6) characteristics of high stress group (e.g. unemployed); 7) characteristics of low stress group (e.g. employed); 8) characteristics shared by both high and low stress groups; 9) percent of the sample that was male; 10) minimum age; 11) maximum age; 12) mean age; 13) ethnicity; name of data source used; 14) geographic location of study sample; 15) baseline start date (day, month, year); 16) baseline end date (day, month, year); 17) follow-up end date (day month, year); 18) maximum follow-up duration; 19) average follow-up duration; 20) information on timing of stress relative to baseline start date; 21) information on the structure of the follow-up period (e.g. were there any gaps between the end of baseline and the beginning of follow-up?); 22) statistical technique used; 23) total number of persons analyzed in the publication; 24) total number of persons analyzed for the specific effect size; 25) number of persons in the high stress group; 26) number of deaths in the high stress group; 27) number of persons in the low stress group; 28) number of deaths in the low stress group; 29) death rate in the high stress group; 30) death rate in the low stress group; 31) effect size; 32) confidence interval; 33) standard error; 34) *t* statistic; 35) Chi-square statistic; 36) minimum value for *p*-value; 37) maximum value for *p*-value; 38) full list of control variables used; 39) date of data extraction; 40) subjective quality rating; 41) number of citations received by publication according to Web of Science; 42) number of citations received according to Google Scholar; 43) 5-year impact factor for place of publication.

Section 3: Additional information on the conversion of odds ratios and relative risks to hazard ratios.

All non-hazard ratio point estimates were converted to hazard ratios (the most frequently reported type) using one or both of the following equations (Zhang & Yu, 1998): $\mathrm{RR} = \mathrm{OR}/((1-r)+(r \times \mathrm{OR}))$ and $\mathrm{HR} = \ln(1-\mathrm{RR} \times r)/\ln(1-r)$, where RR is the relative risk, OR is the odds ratio, HR is the hazard ratio, and *r* is the death rate for the reference (i.e. employed) group.

Section 4: Additional information on the estimation of death rates and standard errors.

Significant predictors of the death rate were follow-up duration, mean age at baseline, sample size (log transformed), an indicator for whether the study statistically controlled for gender, the subjective quality assessment score assigned by the coders, the proportion of the sample that was male, and an indicator for whether the study statistically controlled for age.

Multiple $R = 0.797$. As mortality is the outcome variable in the included studies, it needs to be made explicit that it was the death rate (used to convert different measures of relative risk to a common metric) that was estimated, not the mortality risk estimate itself.

Significant predictors of the standard error were sample size (log transformed), mean age at baseline, follow-up duration, the magnitude of the hazard ratio, and publication date.

Multiple $R = 0.721$.

Section 5: Additional information on method for adjusting inverse variance weights.

Many meta-analysts prefer to use only the most general point estimates reported in a given publication. While this strategy makes it easier to maintain independence between point estimates and makes the calculations of the inverse variance weights straight-forward, it also results in a substantial loss of information. We sought instead to maximize the number of point estimates analyzed, capturing variability both between and within each publication rather than just the former. For example, when a publication (see hypothetical Study X in Table A1) reported mortality risks by gender sub-groups alone the data requires no adjustment. Likewise, when a study reported mortality risks by age group alone (see hypothetical Study Y) the data also requires no adjustment. However, when a publication first reports mortality risks by gender and then again by age (see hypothetical Study Z) this creates a violation of independence because each person is represented twice. To correct for this double-counting, each of the variance weights was adjusted to half of its original value, thus preserving information on the gender and age variables while effectively counting each subject only once.

Table A1
Illustration of adjustments made to the inverse variance weights to correct for double reporting.

Author, publication year	Gender	Age	Original inverse variance weight	Corrected inverse variance weight
Study X	Men only	All ages	4	4
Study X	Women only	All ages	2	2
Study Y	Men only	20-44	5	5
Study Y	Men only	45-65	7	7
Study Y	Men only	65+	3	3
Study Z	Men only	All ages	12	6
Study Z	Women only	All ages	20	10
Study Z	Both men & women	20–44	16	8
Study Z	Both men & women	45–65	24	12
Study Z	Both men & women	65+	16	8

1.0 INTRODUCTION

The purpose of this technical report is to characterize the affected environment for transportation and traffic and anticipated environmental consequences to this resource (transportation and traffic) as a result of the Proposed Action, the Wellsville North Alternative, and the No Action Alternative. Detailed discussions of the description of the Proposed Action, the purpose and need of the Proposed Action, and alternatives to the Proposed Action are provided in the *Purpose and Need and Alternatives Analysis Technical Report* (HDR, 2008a). BNSF Railway Company's (BNSF) preferred site for the proposed intermodal facility is west of Gardner, Kansas. At the request of the U.S. Army Corps of Engineers (USACE), the Wellsville North Alternative has also been brought forward for analysis and comparison. This technical report incorporates comments provided by the Federal Highway Administration (FHWA) and the Kansas Department of Transportation (KDOT) during early coordination with these agencies.

2.0 AFFECTED ENVIRONMENT

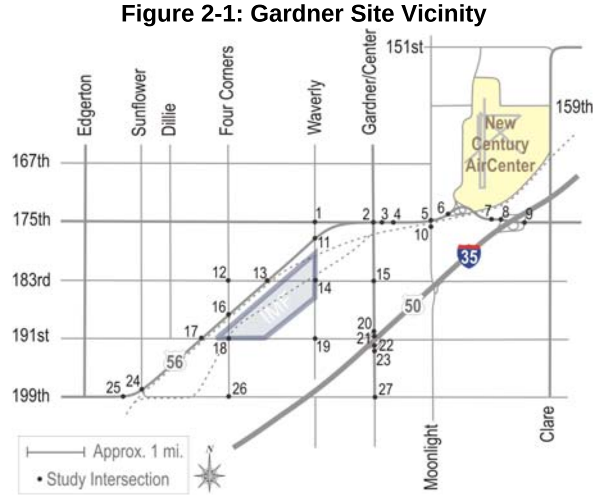
The affected environment section documents the existing transportation system in the vicinity of the Proposed Action and the Wellsville North Alternative. The project area for each site includes the intermodal facility (IMF) footprint (project site) plus off-site rail and roadway improvements. The traffic study areas for the Proposed Action and the Wellsville North Alternative are based on the existing transportation networks in the vicinity of each project site as defined in Sections 2.1.2 and 2.2.2, respectively. This section includes a description of the current roadways, intersections, and rail facilities as well as an assessment of current conditions with respect to traffic volumes, and operations. The affected environments for the Proposed Action and the Wellsville North Alternative are addressed sequentially in the following sections. The methodology used to characterize the affected environment is included in Appendix A.

2.1 Gardner

2.1.1 Gardner Traffic Study Area

The project site is located south of U.S. Highway 56 (US 56) and between 191st Street and Waverly Road, as shown in Figure 2-1. The site is situated southwest of the City of Gardner in unincorporated Johnson County. The traffic study area was the geographic focus for data collection, travel demand forecasting, and traffic operations analysis and is described in Section 2.1.2. This analysis focuses on major roadways and minor roadways expected to carry project-related traffic. A larger area was considered in developing regional assumptions regarding truck distribution patterns. This larger area considered the freeway and interstate system of the entire Kansas City metropolitan area to the extent practical.

Figure 2-1: Gardner Site Vicinity



More important than the development of a geographical study area is the identification of specific facilities (intersections and highway segments) to be analyzed from a traffic operations standpoint. The methodology used in identifying these is described in Appendix A.

2.1.2 Existing Transportation Network in the Vicinity of the Proposed Action

This section describes existing transportation facilities within and near the Gardner traffic study area in 2008. It does not include the 159th Street and Lone Elm Road I-35 interchange that is currently under construction.

Existing Roadway Network

The Gardner traffic study area includes the following roadway and highway facilities, listed in decreasing order of functional classification. Figure 2-2 illustrates the existing roadway network and 2008 average daily traffic (ADT) volumes within the study area.

- *Interstate 35 (I-35)* is a 4-lane interstate highway running northeast-southwest through the study area. It has a posted speed limit of 70 miles per hour (mph). It provides access from Gardner to the rest of the Kansas City metro area. In the vicinity of 151st Street, I-35 widens to six lanes. I-35 currently carries approximately 21,000 to 45,500 vehicles per day (vpd) in the study area.
- *US 56 (Main Street in downtown Gardner)* is a rural 2-lane highway southwest of Gardner, with a posted speed of 55 mph and 2008 volumes of 4,800 vpd or lower. From east of Waverly Road to the US 56/I-35 interchange, it is a 4-lane undivided arterial with posted speeds of 30 to 45 mph. It crosses the BNSF mainline on a grade-separated overpass west of the I-35 interchange. Traffic volumes along this more urban portion of US 56 range from 5,000 to 26,000 vpd.
- *Gardner Road (Center Street in downtown Gardner)* is a 2- to 4-lane collector that provides the main north-south connection between downtown Gardner and I-35. It provides one of two grade-separated crossings of the BNSF tracks in the traffic study area. The grade-separated structure carries one lane in each direction. Traffic volumes on Gardner Road range from 5,000 to 7,000 vpd depending on location.
- *Moonlight Road* is a 2-lane north-south minor collector that carries 8,000 to 11,000 vpd in the vicinity of US 56. Further south, closer to I-35, traffic volumes are considerably lower (2,500 vpd and below). Moonlight Road provides access to the southeastern portions of Gardner and crosses the BNSF mainline tracks at grade less than 150 feet south of US 56.
- *175th Street* (Santa Fe Street, Main Street) coincides with US 56 from 0.5 mile west of Center Street to the I-35 interchange. West of US 56, it is a 2-lane (35 mph) east-west collector providing access to residential developments, Gardner Municipal Airport, and agricultural parcels. East of I-35, 175th Street is also a 2-lane collector. Traffic volumes are shown in Figure 2-2.
- *Waverly Road* is a north-south 2-lane roadway (35 mph). South of US 56, Waverly Road is a gravel road carrying fewer than 150 vpd and providing access to largely undeveloped/agricultural parcels. North of US 56, it is paved, carries volumes of 600 to 1,800 vpd, and provides access to residential areas as well as two schools. Between US 56 and 183rd Street, Waverly Road crosses both BNSF railroad tracks at grade.
- *Four Corners Road* is a paved 2-lane collector (45 mph) extending north from 199th Street through the study area. It crosses the BNSF railroad tracks at grade south of US 56. Within the study area, Four Corners Road carries fewer than 250 vpd.
- *183rd Street* is an east-west 2-lane roadway. From 0.5 mile east of Waverly Road to the west, it is a gravel or chip-sealed road (35 mph) serving undeveloped/agricultural parcels, and crossing both BNSF tracks at grade. To the east, 183rd Street is paved

and provides access to several residential developments. Volumes are shown in Figure 2-2.

- *191st Street* is a low-volume 2-lane 35-mph east-west gravel roadway (with the exception of a short paved section near Gardner Road). It crosses the BNSF tracks at grade east of US 56. At Four Corners Road, 191st Street is offset to avoid crossing the BNSF tracks again. It is also discontinuous on either side of the I-35/Gardner Road interchange.

- *199th Street* is a 2-lane paved collector in the study area. Between US 56/Sunflower Road and Gardner Road, it has a posted speed of 45 mph and crosses the BNSF tracks twice (at-grade) and I-35 once (with a 2-lane overpass). Near US 56, it curves north to meet Sunflower Road. West of this intersection, 199th Street coincides with US 56 as a 2-lane east-west paved roadway. Traffic volumes are shown in Figure 2-2.

- *Sunflower Road* is a paved 2-lane north-south collector located near the west edge of the study area. It connects I-35 with the City of Edgerton; however, it is discontinuous in the vicinity of US 56 and the BNSF tracks. After it turns west to become Nelson Street near Edgerton, the road crosses the BNSF mainline at grade.

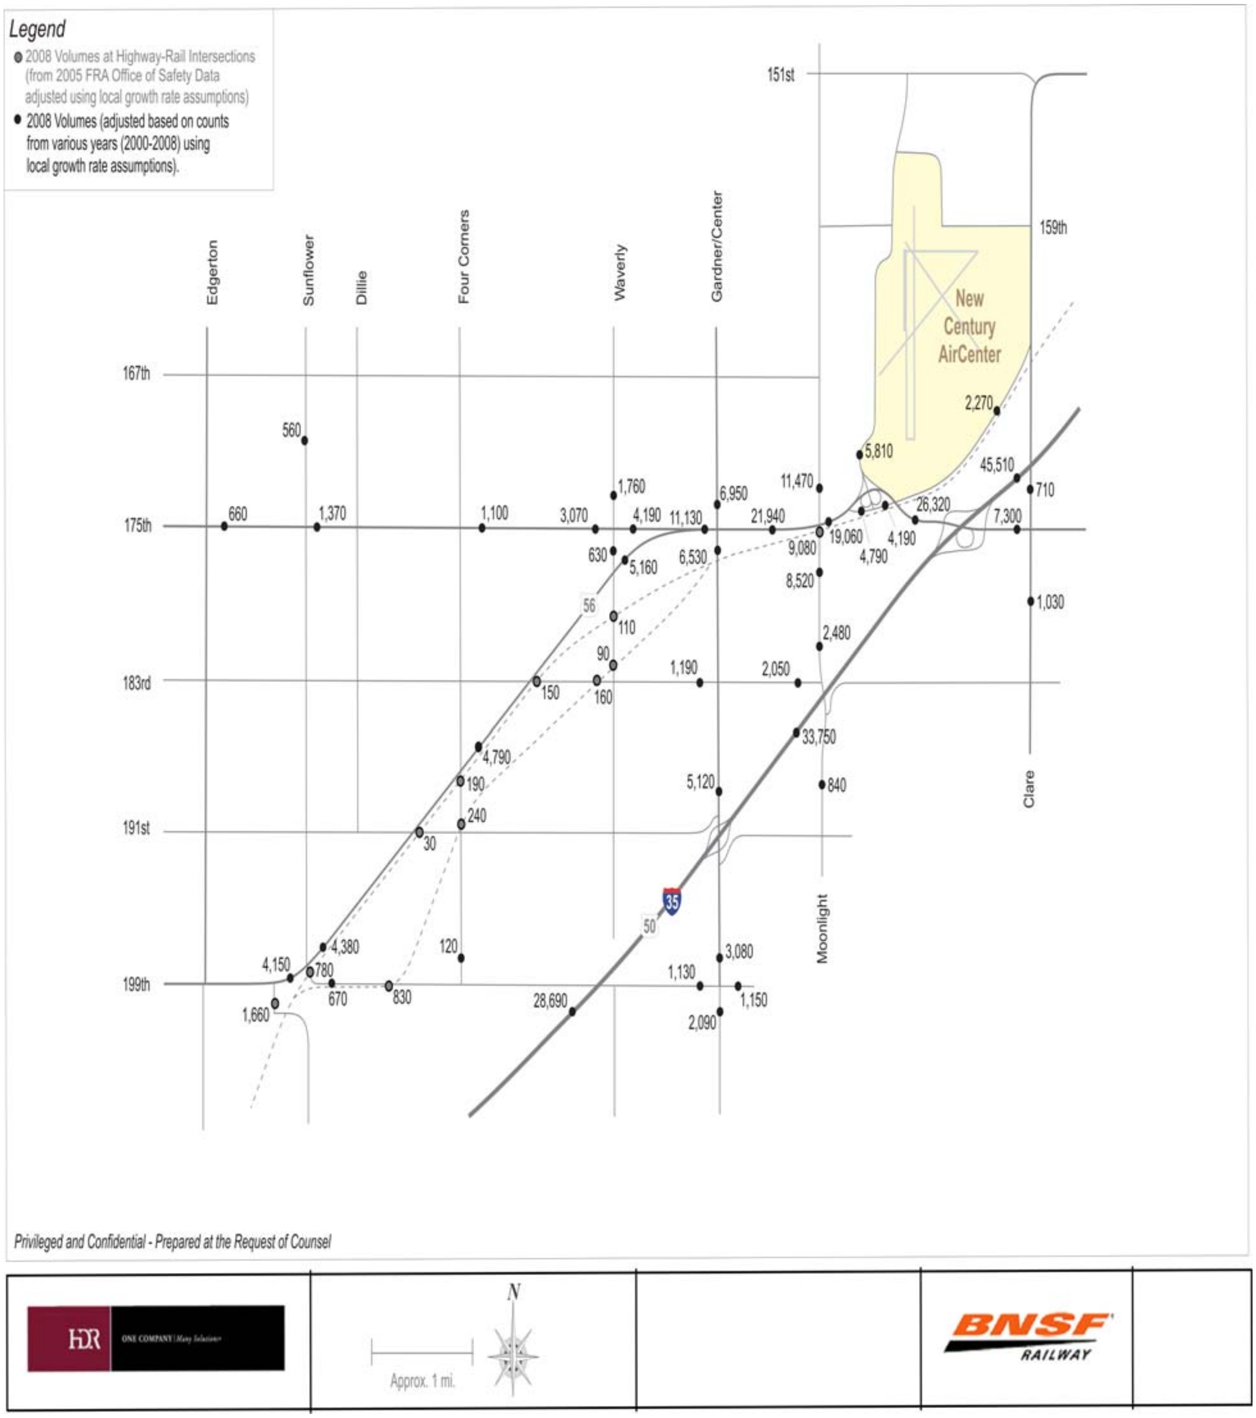
- *Edgerton Road* is a paved north-south collector at the western study area boundary. It provides access to the growing western portion of the City of Edgerton.

The functional classifications and access types for the aforementioned roadways are listed in Table 2-1.

Table 2-1: Gardner Study Area Roadways

Roadway	Functional Classification	Access Control
I-35	Interstate	Full Access Control
US 56	State Arterial Route	Varies (None to Partial)
Gardner Road	Major Collector	None
Moonlight Road	Minor Collector	None
175th Street	Major Collector	None
Waverly Road	Rural Local	None
Four Corners Road	Major Collector	None
183rd Street	Rural Local	None
191st Street	Rural Local	None
199th Street	Major Collector	None
Sunflower Road	Major Collector	None
Edgerton Road	Major Collector	None

Figure 2-2: Existing (2008) ADTs



Existing Interchanges

Three I-35 interchanges are located in the study area and are listed from north to south as follows:

- The I-35/US 56 interchange is approximately 5 miles southwest of the I-35/151st Street interchange. It provides access to and from the City of Gardner and the New Century AirCenter. The interchange is a partial ("one-fourth") cloverleaf configuration with diamond-type ramps for all movements except eastbound to northbound, which has a loop ramp. The diamond ramp intersections are unsignalized.

- The I-35/Gardner Road interchange is approximately 3 miles southwest of the I-35/US 56 interchange. It provides access to the City of Gardner to the north and Miami County to the south. The interchange is a diamond configuration, with Gardner Road as a 2-lane overpass. Both ramp intersections currently operate under stop control.

- The I-35/Sunflower Road interchange is approximately 5 miles southwest of the I-35/Gardner Road interchange. It is a diamond interchange, with Sunflower Road as a 2-lane overpass. The ramp intersections operate under stop control. The interchange provides access to the City of Edgerton to the north and Miami County to the south.

The intersection of US 56 and New Century Parkway is a grade-separated interchange with loop ramps for the eastbound-to-northbound and southbound-to-eastbound movements, and "diamond" ramps for the southbound-to-westbound and westbound-to-northbound movements. All of the ramps are free flow. This interchange primarily serves the New Century AirCenter.

Existing Railroad Network

- Two BNSF mainline tracks of the Emporia Subdivision cross the study area as illustrated in Figure 2-3. *Mainline Track 1 (north track)* is located just south of, and generally parallel to, US 56 between Edgerton to Gardner.
- *Mainline Track 2 (south track)* runs parallel to Track 1, south of Edgerton and north of Gardner, but it diverges away from the north track through the middle of the study area. After crossing Nelson Street, it turns east along the south side of 199th Street to a point approximately 1 mile east of US 56, where it turns northeast, eventually rejoining Track 1 near Center Street.

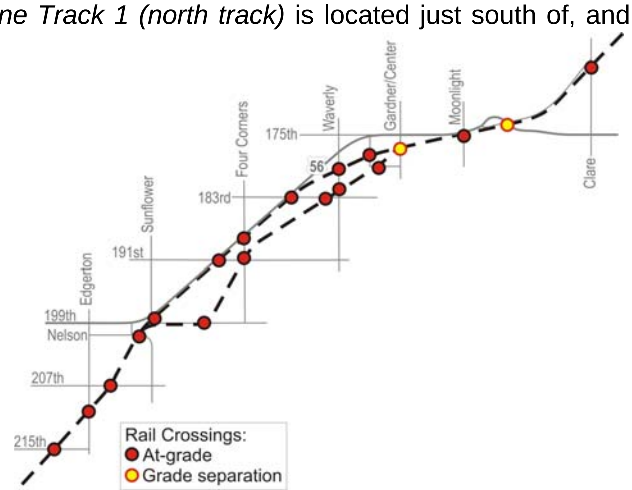


Figure 2-3: Gardner Area Highway-Rail Crossings

The traffic study area includes two grade-separated crossings at Center Street and at US 56 east of New Century Parkway. A third grade-separated crossing located at South Elm Street is currently closed. Thirteen at-grade crossings are located in the study area from Nelson Street to Moonlight Road as shown in Table 2-2. The at-grade crossings at Moonlight Road and Nelson Street include double tracks across the roadway. Table 2-2 lists the thirteen at-grade highway-rail crossings, their Department of Transportation (DOT) crossing numbers, daily train volume, Federal Railroad Administration (FRA) highway ADT estimate, milepost (MP) and track counts. Figure 2-3 shows the at-grade highway-rail crossings listed in Table 2-2.

Table 2-2: At-Grade Highway-Rail Crossings

Roadway	DOT Crossing #	Train Volume (2005)	Highway ADT (2005)	Milepost	Track
Moonlight Road	006162X	82	8,354	33.52	1 & 2
W. Grand Street	006170P	41	6	35.05	2
Poplar Road	006168N	41	64	35.06	1
Waverly Road 1	006178U	41	98	35.61X	1

199th Street 1	006176F	41	714	38.83	1
199th Street 2	006183R	41	767	39.04X	2
Nelson Street	006177M	82	1531	39.77X	1 & 2

<u>Existing Transportation Network Restrictions</u>

Non-passenger vehicles (such as commercial trucks) are prohibited from operating on roadways within the City of Gardner that are not designated as truck routes. This prohibition does not apply to vehicles that are picking-up or delivering at a residence, business, or construction site within the city, provided they take the most direct route to or from a designated truck route. Truck routes include Center Street, 183rd Street/Cherokee Street (west of Center Street), Madison Street, Main Street, Moonlight Road, Sycamore Street (Warren Street to Main Street), Warren Street, and 175th Street. A Kansas Highway Patrol (KHP) weigh station is located on I-35, north of 167th Street. KDOT and KHP are reportedly studying the potential relocation of this weigh station.

2.1.3 Crash History and Conditions

The crash analysis presented in Section 3.1 includes the two main highways in the study area: US 56 and I-35. Crash data were obtained from KDOT's Geometric and Accident Unit in May 2007 (KDOT, 2007). The data include all crashes reported on I-35 and US 56 during the five-year period from 2002 through 2006.

<u>Freeway/Roadway Section Crash Analysis</u>

I-35 and US 56 were subdivided into five smaller sections for the analysis, based on numbers of lanes, traffic volumes, and access control as shown in Table 2-3. Using the KDOT crash data, each of the five sections was examined in detail to highlight any trends or high crash rate locations. Crash totals were then summarized and stratified by severity, crash type, time of day, and roadway conditions to determine the presence of any crash patterns. Crash rates were also calculated for each section and compared to statewide averages.

Total Crashes

A total of 245 crashes occurred on I-35 between Sunflower Road and US 56 during the five-year analysis period. Approximately 64 percent of these crashes occurred between the I-35/Sunflower Road and I-35/Gardner Road interchanges. There were also five fatal crashes during the five-year period on I-35, four of which occurred between Sunflower Road and Gardner Road. A total of 382 crashes were reported on the section of US 56 between Edgerton Road and I-35 during the same time period. Most of these crashes occurred on the high-volume sections of US 56 from just west of downtown Gardner to the I-35 interchange. Only one fatal crash was reported on US 56 in the traffic study area during the 5-year period.

Table 2-3: Crash Summary and Crash Rates along I-35 and US 56

Roadway Section	Length (mi)	Avg. ADT (2002-06)	Crashes Total	Crashes Fatal	Crash Rate (per MVMT) Section Crash Rate	Statewide Average	KDOT Critical Rate[1] (99% conf)	Exceeds Critical Rate
I-35								
1. Sunflower to Gardner	4.714	22,256	156	4	0.815	0.640	0.792	YES
2. e/o Gardner to US 56	3.125	28,502	89	1	0.548	0.640	0.805	NO
US 56								
3. Edgerton to Warren	5.233	4,296	48	1	1.170	1.559	2.073	NO
4. e/o Warren to Cedar	1.475	12,952	148	0	4.245	5.729	6.788	NO
5. e/o Cedar to I-35	1.828	14,898	186	0	3.742	4.556	5.346	NO

Notes: ADT= Average Daily Traffic; MVMT= Million Vehicle Miles Traveled; KDOT= Kansas Department of Transportation.
[1]Critical Crash Rate = the rate that exceeds the statewide average rate at the confidence level specified.

Crash Rates

The Institute of Transportation Engineers (ITE) “Rate Quality Control Method” was employed to conduct a crash rate analysis for all five highway sections. This analysis compares the five-year average crash rate for a particular section to the statewide average for a similar type of highway. Statistical methods were then used to determine if the crash rate exceeds the statewide average (at a 99 percent confidence level) through the use of a critical crash rate threshold.

Table 2-3 shows the crash rates per million vehicle miles traveled (MVMT) for each of the five study highway sections. One section of I-35 between Sunflower Road and Gardner Road was found to exceed the critical crash rate threshold as shown on Table 2-3, indicating that it may be a high crash section. The other four all fall below both the critical threshold as well as the base statewide average for similar facilities. I-35 also had a high fatal crash rate between Sunflower Road and Gardner Road, exceeding the statewide average for fatal crashes. It is not conclusive why this section of I-35 has a higher crash rate, though the data analysis presented in Table 2-4 and in the following sections describes some differences in crash type, time, and roadway conditions.

Crash Severity

The crashes reported within each highway section were examined with respect to severity. Each crash was classified as either fatal, injury, or property damage only (PDO).

The majority of reported crashes were classified as PDO on both roadways (77 percent on I-35 and 74 percent on US 56). Approximately 21 percent of the crashes on I-35 and 26 percent of crashes on US 56 were injury crashes.

Of the total crashes that occurred along I-35, five were fatal crashes (one appeared to involve two fatalities). Four of these crashes occurred between Sunflower Road and Gardner Road, and one occurred between Gardner Road and US 56. During the 2002-2006 time frame, one fatal crash was reported on US 56 at the far western edge of the traffic study area.

Crash Type

An examination of the crash type data for I-35 reveals that the most common crash type was collision with an animal (29 percent). In the high crash rate section south of

Gardner, this type accounted for 31 percent of all crashes. The next most common crash type was collision with a fixed object (26 percent). Overall, crashes with animals and various objects accounted for 59 percent of all crashes on these sections of I-35. The third most common crash type was overturned (12 percent). The various categories of collisions with other vehicles (rear end, sideswipe, angle, etc.) accounted for approximately 23 percent of all I-35 crashes on the two segments evaluated.

Table 2-4: Crash Details along I-35 and US 56

	I-35			US 56				
	Sunflower to Gardner	e/o Gardner to US 56	Totals	Edgerton to Warren	e/o Warren to Cedar	e/o Cedar to I-35	Totals	Grand Totals
Stratified by Severity

Inattentive Driver	8%	18%	11%	19%	26%	21%	13%	12%
Excessive Speed	15%	16%	15%	6%	3%	12%	2%	7%
Drugs/Alcohol	4%	13%	7%	4%	4%	4%	2%	4%
Other	9%	9%	9%	2%	1%	1%	1%	4%
Following Too Closely	3%	0%	2%	2%	10%	13%	4%	3%
Avoidance/Evasive Action	1%	3%	2%	2%	1%	2%	1%	1%

Angle and rear-end crashes accounted for over 80 percent of all crashes on the 4-lane section of US 56 between Gardner and I-35. Further, examination of the subdivided sections revealed that animal crashes accounted for the highest percentage (35 percent) on the western section, followed by rear-end crashes (23 percent). Angle and fixed-object crashes accounted for 13 percent each.

Time of Day

To examine time-of-day patterns, five time periods were established: a.m. off-peak (midnight to 7 a.m.), a.m. peak (7 to 9 a.m.), midday off-peak (9 a.m. to 4 p.m.), p.m. peak (4 to 6 p.m.), and pm off-peak (6 p.m. to midnight). The p.m. off-peak period was the most commonly reported time period for crashes on I-35 (28 percent), with 31 percent of all crashes on the southern segment occurring during that time period. The same was true for the easternmost segment of US 56, where 33 percent of all crashes occurred during the p.m. off-peak period. On the other US 56 segments studied, the most commonly reported period was the midday off-peak (9 a.m. to 4 p.m.), representing over 60 percent of all crashes on those two sections.

Road Surface Conditions

During the study period, dry roads constituted the most common road surface condition, representing 77 percent of total crashes along I-35 and US 56. Wet roadway conditions were present for 15 percent of US 56 crashes (9 percent for I-35), while ice and snow were present for 13 percent of I-35 crashes (3 percent for US 56).

Highway-Rail At-Grade Intersection Crash Analysis

There are currently 13 at-grade highway-rail grade crossings in the Gardner traffic study area from Nelson Street to Moonlight Road. Three are located near Edgerton, seven near the site of the Proposed Action, and three in the vicinity of Gardner as shown in Figure 2-3.

FRA compiles crash data from 1975 to the present for all at-grade rail crossings. It also assigns a crash prediction value, which represents the probability that a collision between a train and a highway vehicle will occur at a crossing in any given year. This value takes into account the crossing's physical and operating characteristics (i.e., ADT, total number of trains per day, number of tracks, maximum time table speed) and five years of crash history data at the crossing.

Table 2-5 presents the at-grade highway-rail crossing crash data and the corresponding prediction crash rate for the period of 2002 through 2006 (FRA, 2007). Between 2002 and 2006, one crash occurred at an at-grade crossing in the traffic study area. The fatality crash occurred at the Waverly Road crossing in 2006. The FRA prediction values for crashes at the locations in the study area range from a high of 0.0568 at Moonlight Road to a low of 0.0033 at 191st Street. Most of the values are below 0.02.

Table 2-5: At-Grade Highway-Rail Crossing Crash Summary

Roadway	DOT Crossing #	# of Crashes	Prediction Crash Rate
Moonlight Road	006162X	0	0.0568
Nelson Street	006177M	0	0.0417

2.1.4 Existing Traffic Conditions

Existing traffic conditions in the traffic study area were assessed based on the current highway volumes, geometrics, and traffic control. The analysis presented below addresses traffic data collection, traffic volumes, traffic operations, and other key traffic issues. Detailed operational calculations are included in Appendix B.

Existing Traffic Data Collection
In order to accurately assess the current traffic conditions, the study team collected a wide range of traffic and highway data. This effort included collecting original field data as well as available existing data from various state and local agencies. Agencies that were contacted included KDOT, Mid-America Regional Council (MARC), Johnson County, Miami County, City of Gardner, and City of Edgerton. The following data were provided by the agencies:

- Detailed daily traffic counts for I-35 and US 56 including truck classification counts where available (KDOT)
- Average daily traffic estimates for over 40 other highway sections (KDOT count map)
- Traffic signal timing for signalized intersections (City of Gardner)
- Crash data for the traffic study area (KDOT)
- Recent traffic studies related to new developments and transportation improvements (various sources)

In addition, weekday a.m. and p.m. peak period intersection turning-movement counts were conducted at 29 study intersections, including the intersections at the three I-35 interchanges as well as 23 additional intersections within the traffic study area. The interchange counts were completed in June/July 2006, while the remaining counts were conducted in April/June 2007. The turning-movement counts were performed during the peak traffic periods of 7:00 to 9:00 a.m. and 4:00 to 6:00 p.m. In addition to the intersection counts, current intersection traffic control and geometry information was collected in the field. Observations were also made regarding current traffic operations at various locations such as the I-35 mainline and ramp termini. Current and forecasted train volumes were obtained from BNSF.

Current average daily traffic counts (from 2002 to 2007) were collected for most of the major roadways in the traffic study area. These counts were adjusted to a consistent base year of 2008.

Traffic Operations Analysis Methodology
The affected environment traffic analysis evaluated existing (2008) operating conditions at 27 study intersections as well as the freeway facilities (mainline and ramp) in the Gardner traffic study area. The analysis focused on the critical weekday a.m. and p.m. peak hours, although daily traffic volume data are presented where appropriate.

The Transportation Research Board's *Highway Capacity Manual* (HCM) method (Transportation Research Board, 2000) is the primary methodology resource used in the traffic operations analysis. The HCM method includes standard analysis methods for intersections, freeways, and ramps (merge and diverge).

Level of service (LOS) is the fundamental HCM parameter describing operational conditions within a traffic stream. LOS is an A-through-F letter ranking scale where LOS A indicates free-flow, low density, or minor delay conditions and LOS F indicates facility breakdown with low speeds, high densities, and high delay. For this study, since the surrounding land use is expected to urbanize during the study time horizon, a minimum standard of LOS D is used as the threshold for acceptable traffic operations. A facility operating below this threshold (at LOS E or F) is considered to be operating unacceptably. Additional details regarding LOS for both intersections and freeway facilities are provided in the methodology discussion in Appendix A.

Existing Intersection Operations

The existing conditions analysis was conducted for the weekday a.m. and p.m. peak hours using the existing traffic volumes, traffic control, and geometry for the study intersections, freeway sections, and freeway ramps. Operations at each of these facilities were examined to identify existing issues. Figure 2-4 illustrates the existing traffic control and geometry and Figure 2-5 illustrates the existing a.m. and p.m. peak-hour volumes used in the analysis. Existing peak hour truck percentages are presented in Appendix C.

Table 2-6 summarizes the results of the existing intersection operational analysis. As indicated in the table, the majority of the study intersections operate at LOS D or better during both peak hours. The following intersections, however, operate below this level:

- *Intersection #5: Moonlight Road and US 56.* This signalized intersection operates at LOS E during the p.m. peak hour, with an average delay of 73.2 seconds per vehicle (sec/veh). The heavy westbound through and right movements (1,373 vehicles combined) conflicting with the north-south flows are the main causes for this delay. In addition, the presence of the BNSF mainline tracks (100 feet to the south of the intersection) with the associated crossing signals, gates, and railroad pre-emption of the vehicular signals leads to additional delay and queuing when the south leg is blocked as discussed in Section 2.1.7.
- *Intersection #6: Old US 56 and US 56*. The northbound left approach to this unsignalized intersection operates at LOS E and F during the a.m. and p.m. peak hours, respectively, largely due to the heavy eastbound through movement in the a.m. peak (1,175 vehicles) and the heavy westbound through movement in the p.m. peak. (1,434 vehicles). Although the northbound approach operates below LOS D, it is a relatively low-volume approach. Approximately 50 and 120 vehicles approach the intersection from the south in the a.m. and p.m. peak hours, respectively.
- *Intersection #8: I-35 Southbound Ramps and US 56.* The one-lane I-35 southbound exit ramp flares to two lanes as it approaches US 56. The heavy southbound right-turn movement has a free-flow lane onto US 56 westbound. The southbound left-turn movement is stop-controlled. This southbound left-turn movement operates at LOS E during the p.m. peak hour, with a volume of 114 vehicles opposed by heavy eastbound and westbound through traffic totaling over 1,600 vehicles.
- *Intersection #10: Moonlight Road and Santa Fe Street.* This intersection is stop-controlled in the northbound and westbound directions. It is also just over 200 feet from the US 56/Moonlight Road intersection; both BNSF mainline tracks cross Moonlight Road between the two intersections. During the p.m. peak hour, the northbound approach to this intersection operates at LOS F due in part to a heavier flow of southbound traffic (approximately 550 vehicles), which does not stop. The short distance between the intersections and the added delay due to trains also affects the operating conditions at this intersection. These same factors also affect operations at the US 56/Moonlight Road intersection.
- *Intersection #15: Gardner Road and 183rd Street.* This intersection is stop-controlled in the eastbound and westbound directions. The westbound left-turn movement operates at LOS E in the a.m. peak hour with an average delay of 41 sec/veh. However, this is a relatively low-volume movement (41 vehicles during the a.m. peak hour; 88 during the p.m.).
- *Intersection #22: Gardner Road and I-35 NB Ramps.* The one-lane eastbound (off-ramp) approach to this unsignalized intersection operates at LOS F during the a.m. peak hour (average delay of 72 sec/veh). This is due, in part, to the conflicting southbound left and northbound right-turn movements, which are heaviest during the a.m. peak. While the level of service for this approach is below LOS D, the volume is modest at approximately 90 vehicles during the a.m. peak hour.

Table 2-6: Study Intersection Existing (2008) Capacity and Operations Analysis Summary

Notes: TWSC – Two-way STOP control, OWSC – One-way STOP control, AWSC – All-way STOP control, LOS – Level of Service.
For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.
Bold indicates a LOS below the acceptable threshold.
[1] The east and south legs are STOP controlled.
[2] The southbound right movement is treated as free flow.

Figure 2-4: Study Area Existing Lane Configuration and Traffic Control

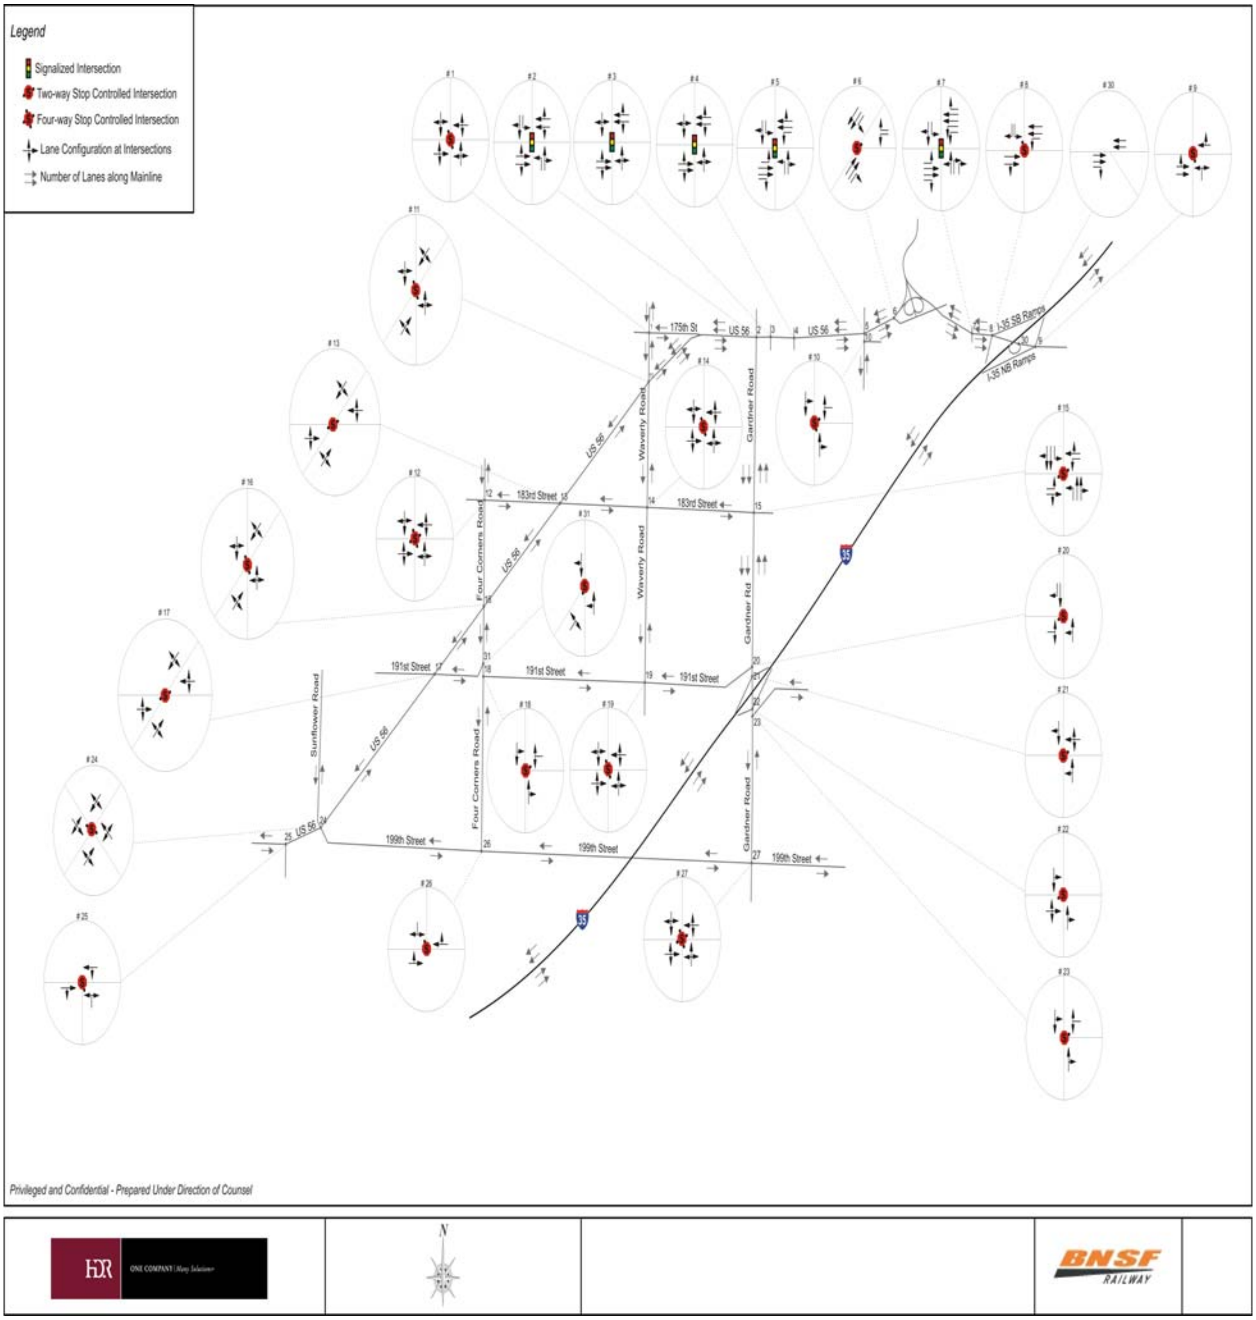

Figure 2-5: Existing (2008) Peak Hour Turning Movement Volumes

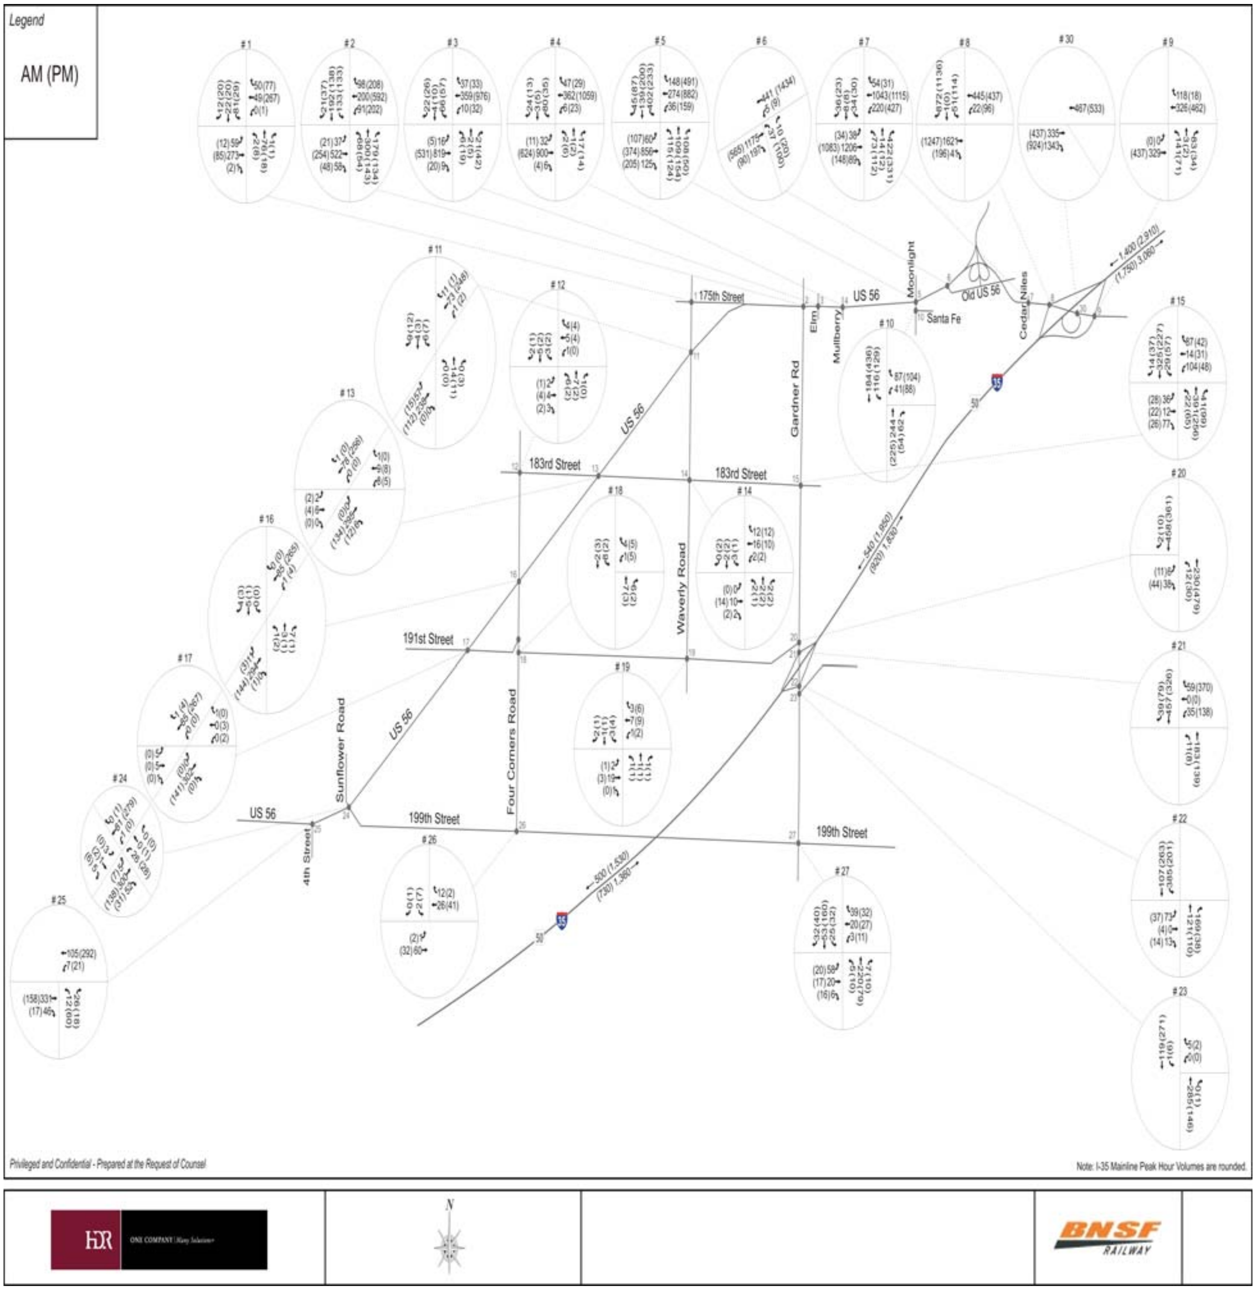

Existing Freeway Operations

The existing I-35 freeway operational analysis (for both mainline and ramp junctions) is summarized in Table 2-7. Currently all freeway segments and ramps in the traffic study area operate at an acceptable LOS (i.e., C or better). Only one freeway segment operates at LOS C (US 56 to 151st Street), while all of the others operate at LOS A or B during both peak periods. Similarly, all of the ramps at the three interchanges in the traffic study area operate at LOS B or better, with the exception of the US 56 on-ramps to I-35 northbound in the a.m. peak and the US 56 southbound off-ramp in the p.m. peak (which operate at LOS C).

Table 2-7: Existing (2008) Freeway Operational Analyses

	AM Peak Hour Density (pc/mi/ln)	AM Peak Hour LOS	PM Peak Hour Density (pc/mi/ln)	PM Peak Hour LOS
Basic Freeway Segments				
I-35 NB				
Sunflower to Gardner	11.2	B	6.3	A

Gardner Entr	5.5	A	14.3	B

Notes: pc/mi/ln – passenger cars per mile per lane, LOS – Level of Service.

2.1.5 Transit

Currently, there is no transit service in the immediate vicinity of the Gardner site. However, transit service in the Gardner area is provided by Johnson County Transit (The JO), as illustrated in Figure 2-6. The main route serving Gardner is Route L (Johnson County Transit, 2008). This is a weekday peak-period express route between the downtown Gardner area and Kansas City, Missouri, with stops at two park-and-ride lots along I-35 north of Gardner. It accesses I-35 via the US 56 interchange. Route L provides three northbound runs to Kansas City in the a.m. peak and three southbound runs from Kansas City in the p.m. peak. The L/N Route also serves the same area with a single late afternoon southbound run from Kansas City each weekday.

Figure 2-6:
Johnson County Transit Route L

2.1.6 Pedestrian and Bicycle Facilities

The roads adjacent to the project area are gravel and do not include specific bicycle or pedestrian facilities. However, there are sidewalks on Gardner Road and on the short new portion of 188th Street just west of Gardner Road. This includes a wide arterial pathway on the east side of Gardner Road from near 191st Street north to West Grand Street.

2.1.7 At-Grade Rail-Highway Crossings and Delay

Table 2-8 highlights 9 key roadways with at-grade highway-rail crossings between Gardner and Edgerton. For each of these crossings, average blocked times and vehicular delays during the a.m. and p.m. peak hours were estimated for the existing train and highway volume conditions (locations where the tracks are separate, such as on 191st Street were treated as one generalized crossing for calculation purposes).

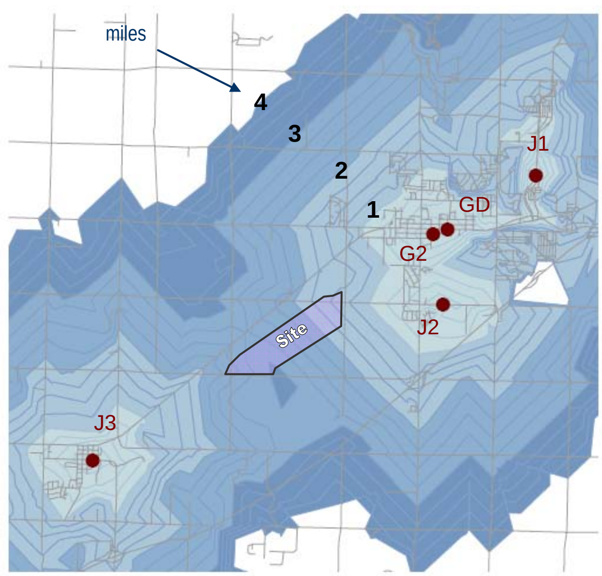
Table 2-8: Gardner Existing Train Crossing Data

		Vehicular Traffic Volume (veh/hr)				Avg. Blocked Crossing Time During Hour (min)		Avg. Delay Per Vehicle (sec)			
		All Vehicles		Vehicles Delayed by Trains				All Vehicles		Delayed Vehicles Only	
Mile		AM	PM	AM	PM	AM	PM	AM	PM	AM	PM
33.52	Moonlight Rd	632	893	96	145	8.2	8.2	13	14	88	87
35.61	Waverly Rd	19	19	3	3	8.2	8.2	12	12	89	89
36.49	183rd St	30	29	4	4	8.2	8.2	12	12	88	87
37.46	Four Corners Rd	12	9	2	1	8.2	8.2	12	12	90	87
38.01	191st St	7	5	1	1	8.2	8.2	12	12	86	90
39.4	199th St	80	62	11	9	8.2	8.2	12	12	87	87
39.77	Nelson St	142	169	21	24	8.2	8.2	13	13	86	88
40.7	207th St	108	108	16	15	8.2	8.2	13	13	86	89
41.2	Edgerton Rd	6	9	1	1	8.2	8.2	12	12	88	87

Approximately 69 trains currently pass through Gardner on the BNSF mainline on an average weekday (Tuesday – Thursday). These trains do not run on fixed schedules; rather, they arrive at various times throughout the 24-hour period. Given the average train length and speed data for this section of track, the average blocked time per train is just under three minutes (this includes gate time before and after each train). Assuming a roughly uniform arrival pattern, the typical average blocked time per hour at each crossing location is approximately eight minutes on an average weekday.

The average delay for all vehicles at each crossing during the a.m. or p.m. peak hours is approximately 12 to 14 sec/veh. The average delay for vehicles that are present when a train is crossing during the a.m. or p.m. peak hours is approximately 86 to 90 seconds per delayed vehicle (approximately one and a half minutes per vehicle). These calculations assume uniform train and highway vehicle arrivals.

Figure 2-7:
Distance from Emergency Response



2.1.8 Emergency Vehicle Access

There are currently two primary entities that provide fire and rescue services in the vicinity of the Gardner site: Johnson County Fire District (FD) No. 1 and Gardner Public Safety Department. Johnson County FD No. 1 serves Southwestern Johnson

County including the City of Edgerton and the unincorporated areas surrounding Edgerton and Gardner. The Gardner Public Safety Department serves the City of Gardner. These two agencies also have a standing inter-agency agreement whereby they support each other in certain circumstances. They also partner with Johnson County Med-Act to provide advanced medical response services. Together, the two local agencies operate a total of five fire/rescue stations in the Gardner/Edgerton area. These stations are listed below and shown in Figure 2-7.

1. Johnson Co. FD No. 1 Station #1 (490 New Century Pkwy – 4 response vehicles) [J1]
2. Johnson Co. FD1 Station #2 (234 East Park Street in Gardner – 3 response vehicles) [J2]
3. Johnson Co. FD1 Station #3 (400 E. 3rd Street in Edgerton – 3 response vehicles) [J3]
4. Gardner Plum Creek Station #2 (29000 E. 183rd Street – 3 response vehicles), opened Feb. ‘08 [G2]
5. Gardner Department of Public Safety (400 E. Main Street) [GD]

Figure 2-8:
Gardner Area Highway Classifications

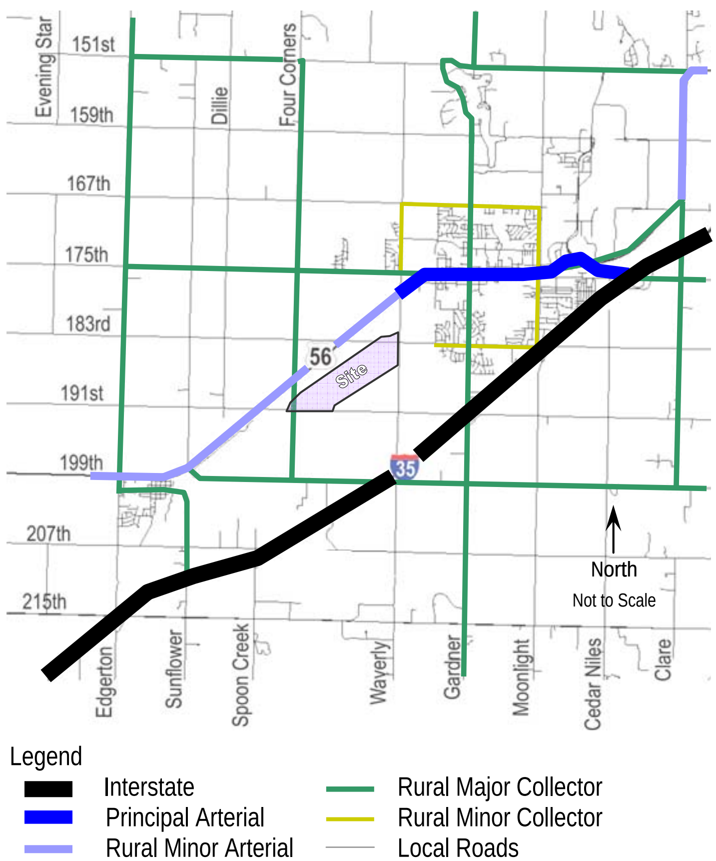


Figure 2-7 shows one, two, three, and four-mile bands around the above five stations. The bands are based on the local roadway network and therefore show actual travel distances from the stations to various areas. From Figure 2-7, it is apparent that the area around the Gardner site is within 4 miles of one or more fire/rescue stations.

Emergency vehicle responders have the potential of being delayed if a train is present at the mainline crossing. The actual delay time would depend entirely on the specific conditions (i.e., emergency vehicle arrival time relative to the train arrival time as well as the length and speed of the train). However, the total blocked-time delay due to a single train, based on the average speed data provided by BNSF, is approximately 2.2 minutes (excluding flashing light and gate time).[1] Currently, the Gardner-based stations can serve both sides of the track without additional delay by using the Center Street Bridge. Emergency responders from the Edgerton station to the south and southwestern Gardner areas must cross the BNSF tracks at-grade to reach the areas east of US 56 unless they go substantially out of their way to Center Street in Gardner.

[1] This is the average time a train blocks this crossing, not the average delay for vehicles, as not all vehicles are blocked the total time the train occupies the crossing.

2.1.9 Circulation System

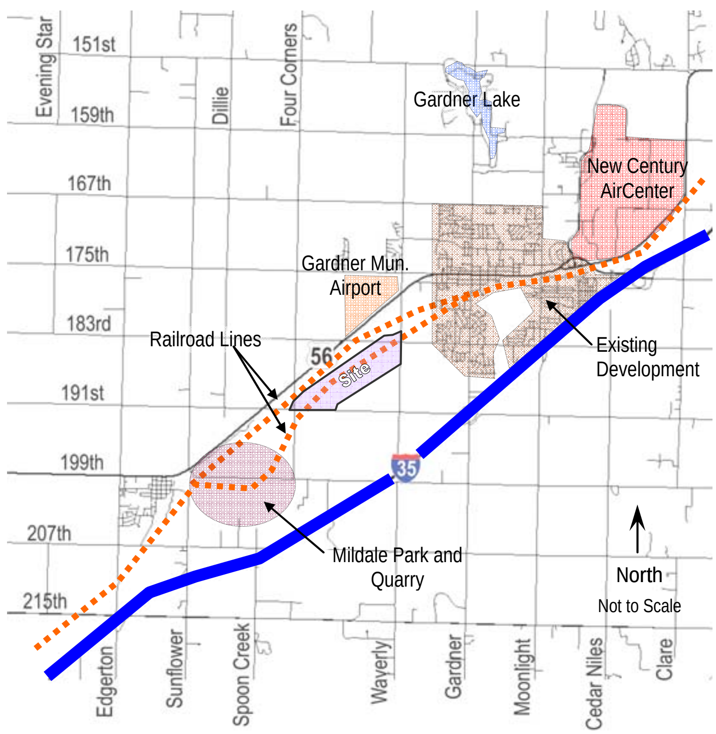
There are three major subtopics related to the existing local highway circulation system in the vicinity of the Gardner site: system form, connectivity, and barriers.

The circulation system in the vicinity of the Proposed Action is generally a grid system as shown in Figure 2-8. The grid spacing is approximately one mile between roadways in the undeveloped areas. In the developed portions of Gardner and Edgerton, there is a combination of tight grid network (older development) and curvilinear roadways with cul-de-sacs (newer development). US 56 and I-35 both cut through the grid system at an angle, but because I-35 has access only at interchanges it provides regional, but not local, connectivity.

The current roadway hierarchy has been developed such that arterial and collector roadways carry higher local traffic volumes and essentially serve as the backbone of the local system. These higher classification facilities, combined with the remaining grid system, provide local network connectivity, including connections to I-35 - which, in turn, provides the major connection to the larger region.

Based on KDOT's and MARC's most recently published highway classification information, US 56 is classified as an arterial highway - Principal Arterial in Gardner and Minor Arterial west of Gardner. Gardner Road/Center Street and 199th Street (east of US 56) are both classified as Rural Major Collectors. Four Corners Road and 175th Street (west of US 56) are also classified as Rural Major Collectors. The remaining roadways are unclassified in MARC's current hierarchy. However, as a practical consideration portions of Moonlight Road, 183rd Street, and 167th Street could be classified as Rural Minor Collectors. The remaining road-ways would then be classified (at present) as Local Roadways.

Figure 2-9:
Gardner Area Barriers to Local Transportation



The transportation system barriers addressed in this report are physical features (natural or man-made) that block or inhibit new connections between local transportation facilities. For example, a creek is a natural transportation barrier. Connecting roadways on different sides of a creek requires the construction of a bridge or culvert. Some of the current highway system barriers include I-35, existing development, railroad lines, New Century AirCenter, Mildale Park, Gardner Municipal Airport, and local creeks and streams. A number of these are shown in Figure 2-9. These barriers are penetrated to various extents (for example there are many railroad and stream crossings), but each could be a barrier to future highway system development.

2.2 Wellsville North Alternative

2.2.1 Wellsville North Traffic Study Area

Figure 2-10: Wellsville North Alternative Site Vicinity

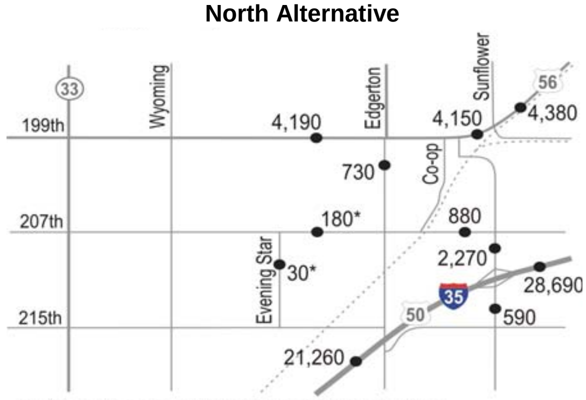
The Wellsville North site is located to the west of Edgerton Road to nearly Wyoming Road; and north of I-35 and the BNSF mainline to approximately ¼ mile north of 215th Street as shown in Figure 2-10. The project site is situated to the southwest of the City of Edgerton and northeast of Wellsville in unincorporated Johnson County and Miami County. A traffic study area surrounding the site was defined and analyzed for potential traffic impacts. The Wellsville North traffic study area is generally bounded by Kansas Highway 33 (K-33) to the west, 223rd Street to the south, Gardner Road to the east, and 175th Street to the north.

While the traffic study area was the geographic focus for data collection, travel demand forecasting, and traffic operations analysis, this analysis focused on major roadways and minor roadways expected to carry project-related traffic.

As in the analysis of the Proposed Action, a larger area was considered in developing regional assumptions regarding truck distribution patterns associated with the Wellsville North Alternative. This larger area considered the freeway and interstate system of the entire Kansas City metropolitan area to the extent appropriate.

2.2.2 Existing Transportation Network in the Wellsville North Alternative Vicinity

Figure 2-11: Existing ADTs –Vicinity of Wellsville North Alternative

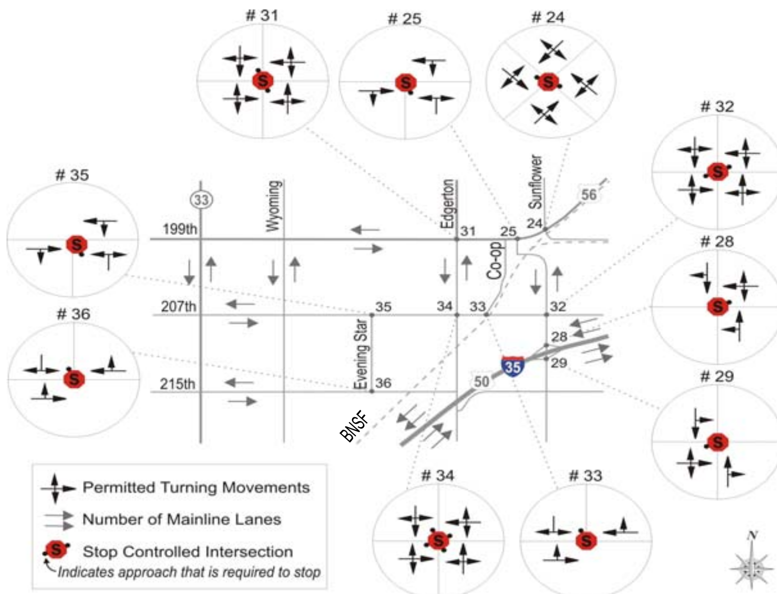


*Estimated based on existing turning movement counts

The Wellsville North traffic study area includes the roadways in the Gardner study area plus the additional highway facilities listed below, presented in decreasing order of functional classification. Figure 2-11 contains the existing ADT volumes in the Wellsville North study area. Figure 2-12 illustrates the existing roadway network geometry and traffic controls at the Wellsville North study intersections (except intersections 1, 2, 11, 13, 16, 17, and 26 which were presented in Figure 2-4).

- *I-35* is a 4-lane interstate highway running northeast-southwest through the study area. It has a posted speed limit of 70 mph. I-35 carries approximately 21,000 to 29,000 vpd in the study area.

Figure 2-12: Existing Geometry and Traffic Control – Wellsville North Alternative



- *US Route 56 (US 56)/199th Street* is a two-lane highway, with a posted speed varying between 45 mph and 55 mph, and 2008 volumes of 4,400 vpd or lower. The portion of US 56 that is included in the Wellsville North study area extends from approximately K-33 in the southwest to Center Street/Gardner Road in the northeast.
- *Sunflower Road* is a two-lane paved collector providing the primary north-south connection between the City of Edgerton and I-35. Sunflower Road curves and becomes Nelson Road within the City. Sunflower Road/Nelson Road has one of the two at-grade railroad crossings in the Edgerton area. Traffic volumes on Sunflower Road are lower than 2,300 vpd depending on location.
- *Edgerton Road (West 8th Street in Edgerton)* is a two-lane paved collector north of 207th Street, and a gravel roadway south of 207th Street. Edgerton Road provides the secondary north-south connection between US 56 and 207th Street, giving access to the community on the west side of Edgerton. To the south of 207th Street, Edgerton Road crosses the BNSF railroad tracks. Edgerton Road carries approximately 700 vpd within the study area.
- *207th Street* is a two-lane paved local road running east-west through the study area. An at-grade rail crossing exists on 207th Street between Edgerton Road and Sunflower Road. This roadway provides access to I-35 for residents in the western part of Edgerton. Volumes on 207th Street range from 180 to 880 vpd depending on location.
- *215th Street* is an east-west two-lane gravel road. There is currently an at-grade rail crossing on 215th Street between Evening Star Road and Edgerton Road. This roadway serves agriculture/undeveloped land.
- *Evening Star Road* is a north-south two-lane gravel roadway connecting 207th Street and 215th Street. Existing daily volumes are very low, as shown in Figure 2-11.
- *Co-op Road (East 2nd Street in Edgerton)* is a two-lane paved local roadway running along the southeastern portion of the City of Edgerton, paralleling the BNSF railroad. This roadway serves some local homes and the Ottawa Cooperative Association grain elevator.

The Wellsville North analysis also evaluated the I-35/Sunflower Road interchange that was not included in the Gardner analysis. However, the I-35/K-33 interchange, which is located approximately five miles southwest of the I-35/Sunflower Road interchange, was not included in the Wellsville North analysis. The K-33 interchange provides access to the City of Wellsville to the north and to the City of Rantoul approximately 12 miles to the south. This interchange was not evaluated because little to no project traffic is anticipated to use it.

2.2.3 Wellsville North Existing Conditions Analysis

The existing conditions analysis was conducted in a manner similar to the Gardner analysis utilizing the existing traffic volumes, traffic control, and geometry to analyze the study intersections, freeway sections, and freeway ramps. The general overall operations at each of these transportation facilities were examined for deficiencies. Figure 2-13 illustrates the existing a.m. and p.m. peak-hour volumes used in the analysis (except intersections 1, 2, 11, 13, 16, 17, and 26 which were presented in Figure 2-5). Existing peak-hour truck percentages are presented in Appendix C, and detailed operational results are included in Appendix D.

Existing Intersection Operations

Table 2-9 summarizes the results of the existing intersection analysis for the Wellsville North Alternative. The study intersections generally carry low volumes and are mainly unsignalized. Most of the study intersections currently operate at LOS C or better during the both peak hours. The one exception is the unsignalized intersection of US 56 and the Southbound I-35 Ramps. At this intersection, the one-lane I-35 southbound exit ramp flares to two lanes as it approaches US 56. The heavy southbound right-turn movement has a free-flow lane onto US 56 westbound. The southbound left-turn movement is stop-controlled. This southbound left-turn movement operates at LOS E during the p.m. peak hour, with a volume of 114 vehicles opposed by heavy eastbound and westbound through traffic totaling over 1,600 vehicles.

Table 2-9: Wellsville North Study Intersection Existing (2008) Capacity and Operations Analysis Summary

Study Intersection # and Name	Traffic Control	AM Peak Hour Delay (sec/veh)	AM Peak Hour LOS	PM Peak Hour Delay (sec/veh)	PM Peak Hour LOS

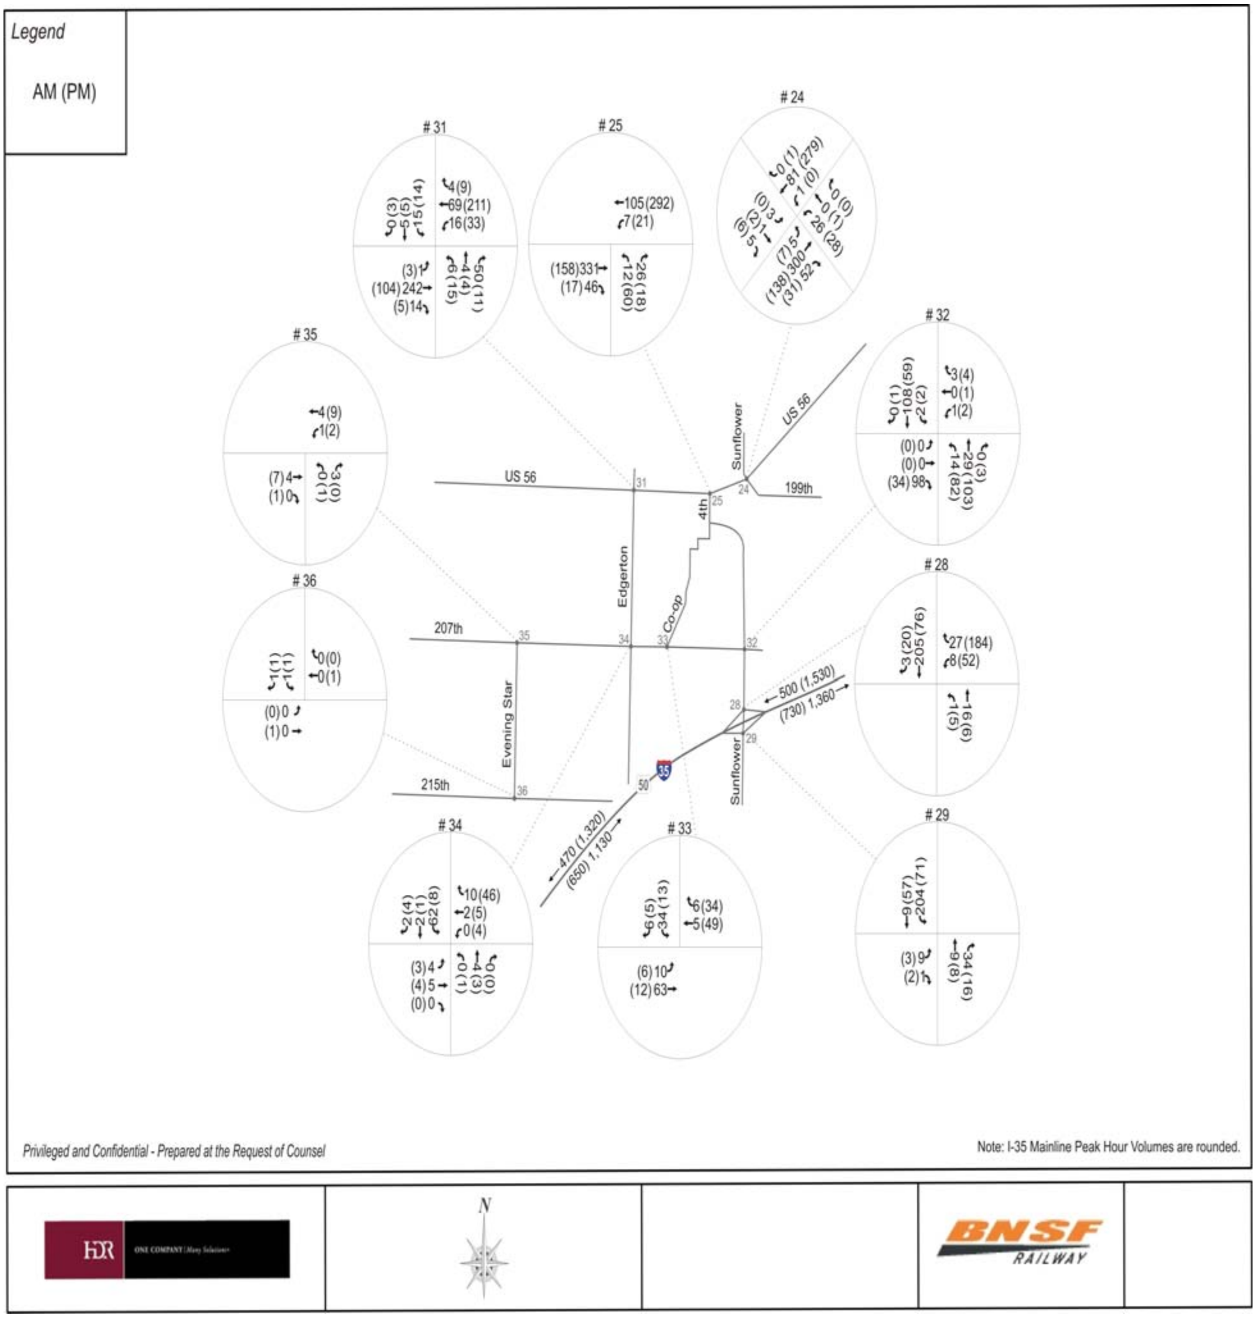
Notes: TWSC – Two-way STOP control, OWSC – One-way STOP control, AWSC – All-way STOP control, LOS – Level of Service.
Bold indicates a LOS below the acceptable threshold.
For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.
[1] The southbound right movement is treated as free flow.

Figure 2-13: Wellsville North Study Intersection Peak Hour Turning Movement Volumes



Existing Freeway Operations

In addition to the Gardner area freeway facilities described in Section 2.1.2, the analysis for the Wellsville North Alternative evaluated the I-35 mainline south of Sunflower Road as well as the I-35/Sunflower Road interchange ramps. As shown in Table 2-10 these additional freeway facilities all currently operate at LOS B or better.

Table 2-10: Existing (2008) Freeway Operational Analyses

Notes: pc/mi/ln – passenger cars per mile per lane, LOS – Level of Service.

Existing Railroad Network

Throughout the Wellsville North study area there are a number of rail crossings. These at-grade rail crossings generally include two parallel mainline tracks and are mostly located on low-volume gravel roads. The locations and alignments of the two mainline tracks are discussed in *Existing Railroad Network*, Section 2.1.2.

The Wellsville North traffic study area includes one grade-separated crossing on K-33 south of East 7th Street in Wellsville. There are seven at-grade crossings (five of which include double tracks across the roadway), from 223rd Street to 199th Street. Table 2-11 lists the seven at-grade highway-rail crossings, their DOT crossing numbers, daily train volume, FRA highway-ADT estimate, MP, and track. Figure 2-14 illustrates the at-grade highway-rail intersections included in Table 2-11.

Table 2-11: Wellsville North Study Area At-Grade Highway-Rail Crossings

Roadway	DOT Crossing #	Train Volume (2005)	Highway ADT (2005)	Milepost	Track
199th St 1	006176F	41	714	38.83	1
199th St 2	006183R	41	767	39.04X	2

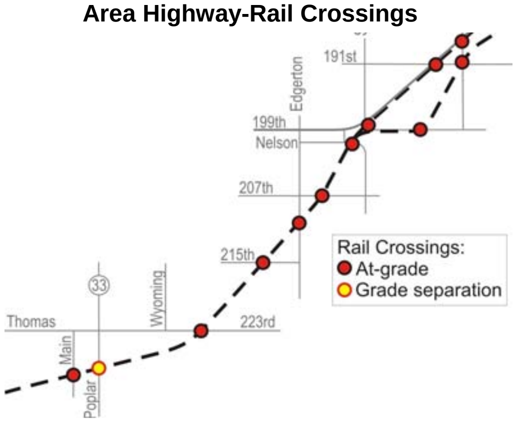
Figure 2-14: Wellsville North Study Area Highway-Rail Crossings



Highway-Rail At-Grade Intersection Crash Analysis

As with the Gardner analysis, the Wellsville North crash analysis uses FRA crash data and prediction values. Between 2003 and 2007, three crashes occurred at at-grade crossings in the Wellsville North study area. The 223rd Street crossing involved an injury while the other 207th Street crashes were PDO. Table 2-12 presents the at-grade rail crossing crash data for 2003 through 2007 as well as the corresponding prediction crash rate (FRA, 2008). The prediction values for crashes at the locations in the study area range from a high of 0.3492 at 207th Street to a low of 0.0054 at 215th Street.

Table 2-12: Wellsville North At-Grade Highway-Rail Crossing Crash Summary

Roadway	DOT Crossing #	# of Crashes	Prediction Crash Rate
207th Street	006184X	2 (2003 PDO, 2007 PDO)[1]	0.3492
Edgerton Road	006185E	0	0.2321
215th Street	006187T	0	0.0054
223rd Street	006190B	1 (2004 Injury)	0.0194

Notes:
[1] PDO means Property Damage Only.

2.2.4 Transit

Currently, there are no transit services in the immediate vicinity of the Wellsville North Alternative, the City of Edgerton, or the City of Wellsville.

2.2.5 Pedestrian and Bicycle Facilities

The roads adjacent to the project site are gravel and do not include specific provisions for either bicycles or pedestrians. The paved roads providing access to the site are rural roads also without specific provisions for bicycles or pedestrians.

2.2.6 At-Grade Rail-Highway Crossings and Delay

The current blocked time and crossing delay described previously for the Edgerton area locations also applies to Wellsville North. In addition, there are three crossings in Wellsville presented in Table 2-13. As with the Edgerton area data, the average blocked time per train is just under three minutes (including flashing light and gate time). Approximately eight minutes per hour are blocked on average during a typical weekday. The average delay per vehicle is 12 to 13 seconds for all vehicles and 86 to 88 for delayed vehicles.

Table 2-13: Additional Wellsville North Existing Crossing Data

		Vehicular Traffic Volume (veh/hr)				Avg. Blocked Crossing Time During Hour (min)		Avg. Delay Per Vehicle (sec)			
		All Vehicles		Vehicles Delayed by Trains				All Vehicles		Delayed Vehicles Only	
Mile		AM	PM	AM	PM	AM	PM	AM	PM	AM	PM
42.03	215th	1	3	0	0	8.2	8.2	12	12	85	87
43.39	223rd	8	9	1	1	8.2	8.2	12	12	88	88
45.45	Main	166	185	24	27	8.2	8.2	13	13	88	88

2.2.7 Emergency Vehicle Access

Two primary entities provide fire and rescue service in the vicinity of the Wellsville North Alternative. The first is the Wellsville Fire Department, which has an agreement with Miami County FD No. 1 to provide service in Miami County near Wellsville. The second is Johnson County FD No. 1 Station #3 in Edgerton. The two stations are located at:

1. Wellsville Fire Station (730 S. Main Street) [W]
2. Johnson Co. FD1 Station #3 (400 E. 3rd Street in Edgerton) [J3]

Figure 2-15: Distance from Emergency Response

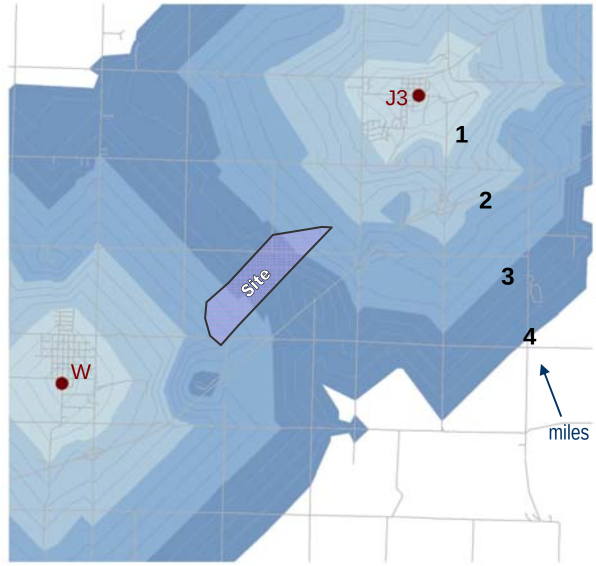


Figure 2-15 illustrates service distance bands (from 1 to 4 miles) around the two stations. The Wellsville North site is within four miles of one or both of the two stations.

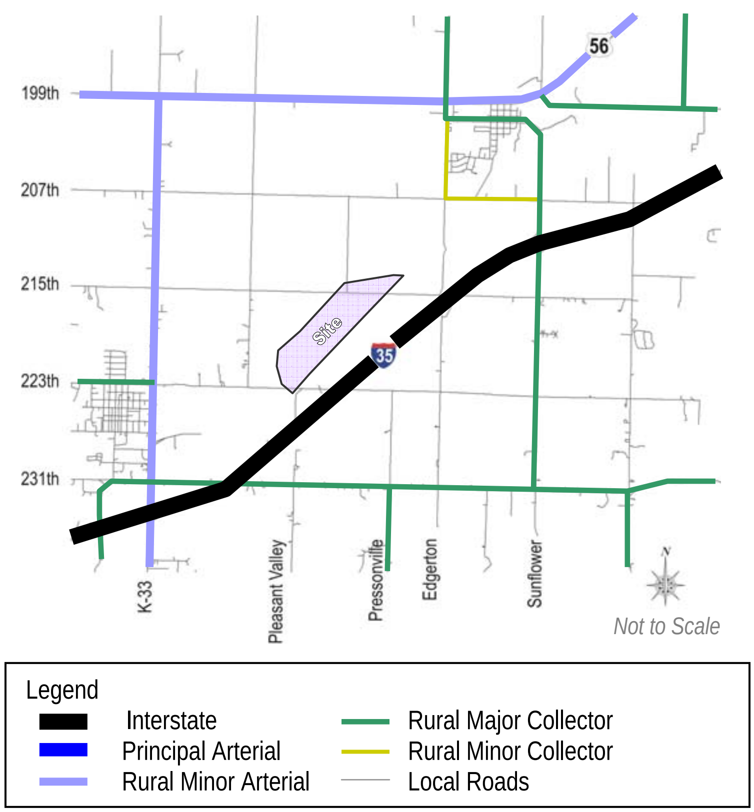
Similar to Gardner, emergency vehicle responders have the potential of being delayed if a train is present at a crossing. The actual delay time would depend on the specific conditions (i.e., emergency vehicle arrival time relative to the train arrival time as well as the length and speed of the train). However, the total blocked-time delay due to a single train, based on the average speed data provided by BNSF, is approximately 2.2 minutes (excluding flashing light and gate time). Currently, the Wellsville-based station is the only station that can serve both sides of the tracks without additional delay by using the Poplar Street bridge. Responders from the Edgerton station must cross the BNSF tracks at-grade to reach the areas east of the tracks.

Figure 2-16: Wellsville North Area Highway Classifications



2.2.8 Circulation System

The area around the Wellsville North Alternative project site has many similarities to the Gardner project site vicinity in terms of highway form, connectivity, and barriers. The Wellsville North Alternative project site is located within a rural grid system with approximately 1-mile spacing between roadways. In the vicinity of Edgerton, there is an older, denser highway grid near the center of town as well as more recent curvilinear roadways to the west and south of town. Figure 2-16 illustrates the circulation system in this area.

Major local connectivity in the area is provided by a set of arterial and collector roadways. The MARC classification system ends at the Johnson County border and the classification information for the surrounding counties does not completely match with the MARC or KDOT systems. Therefore, a hybrid classification network is presented in Figure 2-16. This figure is not completely consistent with all of the state or local plan maps, but it captures the practical functionality of the roads in the area in a consistent way for purposes of this analysis. As shown in the figure, US 56 serves as a rural minor arterial and Edgerton Road (north of Nelson Street), Nelson Street, Sunflower Road, 231st Street, and a few others serve as rural major collector roadways. Other roadways, such as Edgerton Road between 207th and Nelson Street and 207th from Edgerton Road to Sunflower Road, could be deemed minor collector roadways. The remaining roadways are local roadways.

Barriers in the Wellsville North area include I-35, existing development, railroad lines, parks, and streams. Again, many of these are somewhat permeable barriers, but all can present challenges to future highway connectivity.

3.0 ENVIRONMENTAL CONSEQUENCES

Direct effects to transportation were determined by evaluating the anticipated effects based on construction and opening year (2010) operation of the Proposed Action and Wellsville North Alternative. Indirect effects were evaluated for each project area by considering the following: future operations of the IMF (through 2030) and development anticipated to be induced by the IMF. For the Proposed Action, induced development consists of the Logistics Park Kansas City, as described in this section. For the Wellsville North Alternative, the exact nature of induced development is not known and therefore was not analyzed.

For the Proposed Action, the study team in collaboration with the federal, state, and local agencies decided that the Olathe Traffic Model (OTM) was reasonable for forecasting long-term (2030) traffic growth in the vicinity of the proposed Gardner IMF and land uses planned by local jurisdictions. The OTM is a computerized travel demand forecasting model developed and refined by the City of Olathe, Kansas. As a part of the demand modeling process, model input assumptions must be made regarding land use and future network changes. Review agencies, including KDOT, the City of Gardner, the City of Edgerton, Johnson County, Miami County, and MARC assisted in the determination of these assumptions. At its core, the model consists of a computerized representation of the roadway/highway network, plus an overlay of 782 Traffic Analysis Zones (TAZs) in which land-use quantities are aggregated to generate traffic volumes. For the traffic analysis, a “forecasting focus area” was defined in which land use and network adjustments could be made to refine model accuracy. Given the input of the local planning entities with regard to land use assumptions and forecasts for the OTM, this forecasting focus area was used for the indirect and cumulative effects analyses. In addition, a few large-scale projects outside of the forecasting focus area were also included in the cumulative effects analysis based on discussions with public agencies. These projects are discussed in the *Cumulative Effects Technical Report* (HDR, 2008b).

The Wellsville North development area is located southwest of the Gardner development area and outside of the boundaries of the OTM forecasting focus area as well as outside of the entire OTM planning area. As a result, quantified land use forecasts for the reasonably foreseeable future are not available.

To establish a basis against which to compare the Proposed Action and Wellsville North Alternative scenarios, No Action scenarios that anticipate planned land-use growth and associated roadway/highway improvements were created. The IMF is not included as a development in the No Action scenarios. Development and evaluation of the No Action scenarios (coupled with results of the Proposed Action and Wellsville North Alternative scenarios) allows the identification of direct project traffic impacts, if any. To evaluate direct effects from the Proposed Action and Wellsville North Alternative, the scenarios were compared for opening year (2010).

Induced development includes a proposed logistics park, Logistics Park Kansas City adjacent to BNSF's planned IMF at Gardner. The logistics park would be developed by The Allen Group – Kansas City (TAG-KC) and consist of 400,000 to 600,000 square feet of speculative freight distribution and warehouse space available for lease around the same time that BNSF's IMF opens. TAG-KC has projected that it might construct additional warehouse capacity (up to 2.86 million square feet) sometime between 2010 and 2015 depending on demand in the South Johnson County market (William Crandall Verified Statement [Crandall VS], 2008). To evaluate indirect effects associated with future operations of the IMF and development anticipated to be induced by the IMF, the horizon years for analysis were expanded to include 2015 and 2030.

Because the surrounding land use is expected to urbanize during the study time horizon, a minimum standard of LOS D was used as the threshold for acceptable traffic operations for freeway facilities and intersections. A significant impact would exist if an unacceptable LOS (i.e., E or F) was predicted to occur on a state or major route in 2010 (opening year) or in 2015 (5 years after opening). Appropriate mitigation measures are discussed in the *Mitigation Technical Report* (HDR, 2008c).

3.1 Direct Effects - Gardner

3.1.1 2010 Gardner No Action

<u>2010 Gardner No Action Forecast Volumes</u>
The 2010 Gardner No Action scenario is a near-term scenario for comparing opening day for the build scenarios. It assumes modest near-term traffic growth consistent with historical growth in the area. Based on KDOT vehicle count data, and consistent with the recently completed *I-35 Gardner Break-in-Access* (BIA) Study (HDR, 2007), a growth rate of 2.8 percent per year was assumed for intersections and a growth rate of approximately 3.2 percent per year was assumed for the I-35 mainline. These growth rates were applied to the existing (2008) volumes.

The resulting 2010 No Action ADT volumes and peak-hour turning movement volumes are illustrated in Figures 3-1 and 3-2. The volumes are rounded, reflecting the fact that they are forecasts. Peak-hour truck percentages are presented in Appendix C.

<u>2010 Gardner No Action Geometry Assumptions</u>
In 2010, the roadway network geometry was assumed to be similar to the existing network geometry, with a few notable exceptions as described below:

- *I-35/Gardner Road Interchange and Vicinity* – By 2010, KDOT is planning to improve the interchange by signalizing both ramp intersections, widening to add westbound and southbound turn lanes at the southbound ramp intersection (#21), and widening Gardner Road to four lanes from the I-35 southbound ramps north to 191st Street.

- *Moonlight Road Improvements* – The City of Gardner has plans to improve Moonlight Road near Main Street (US 56) by 2010. This includes widening Moonlight Road to four lanes and adding turn lanes at Main Street and Santa Fe Street. It also includes relocating Santa Fe Street further to the south to improve the distance between it and the railroad tracks and Main Street. The Moonlight Road/Santa Fe Street intersection is also expected to be signalized.

- *Improvements to Meet No Action Demand* – In addition to the improvements described above, several other modest improvements may be required for acceptable operations under the No Action scenario. These improvements address projected No Action scenario deficiencies and are discussed further in the operational analysis section.

Figure 3-1: 2010 Gardner No Action ADTs

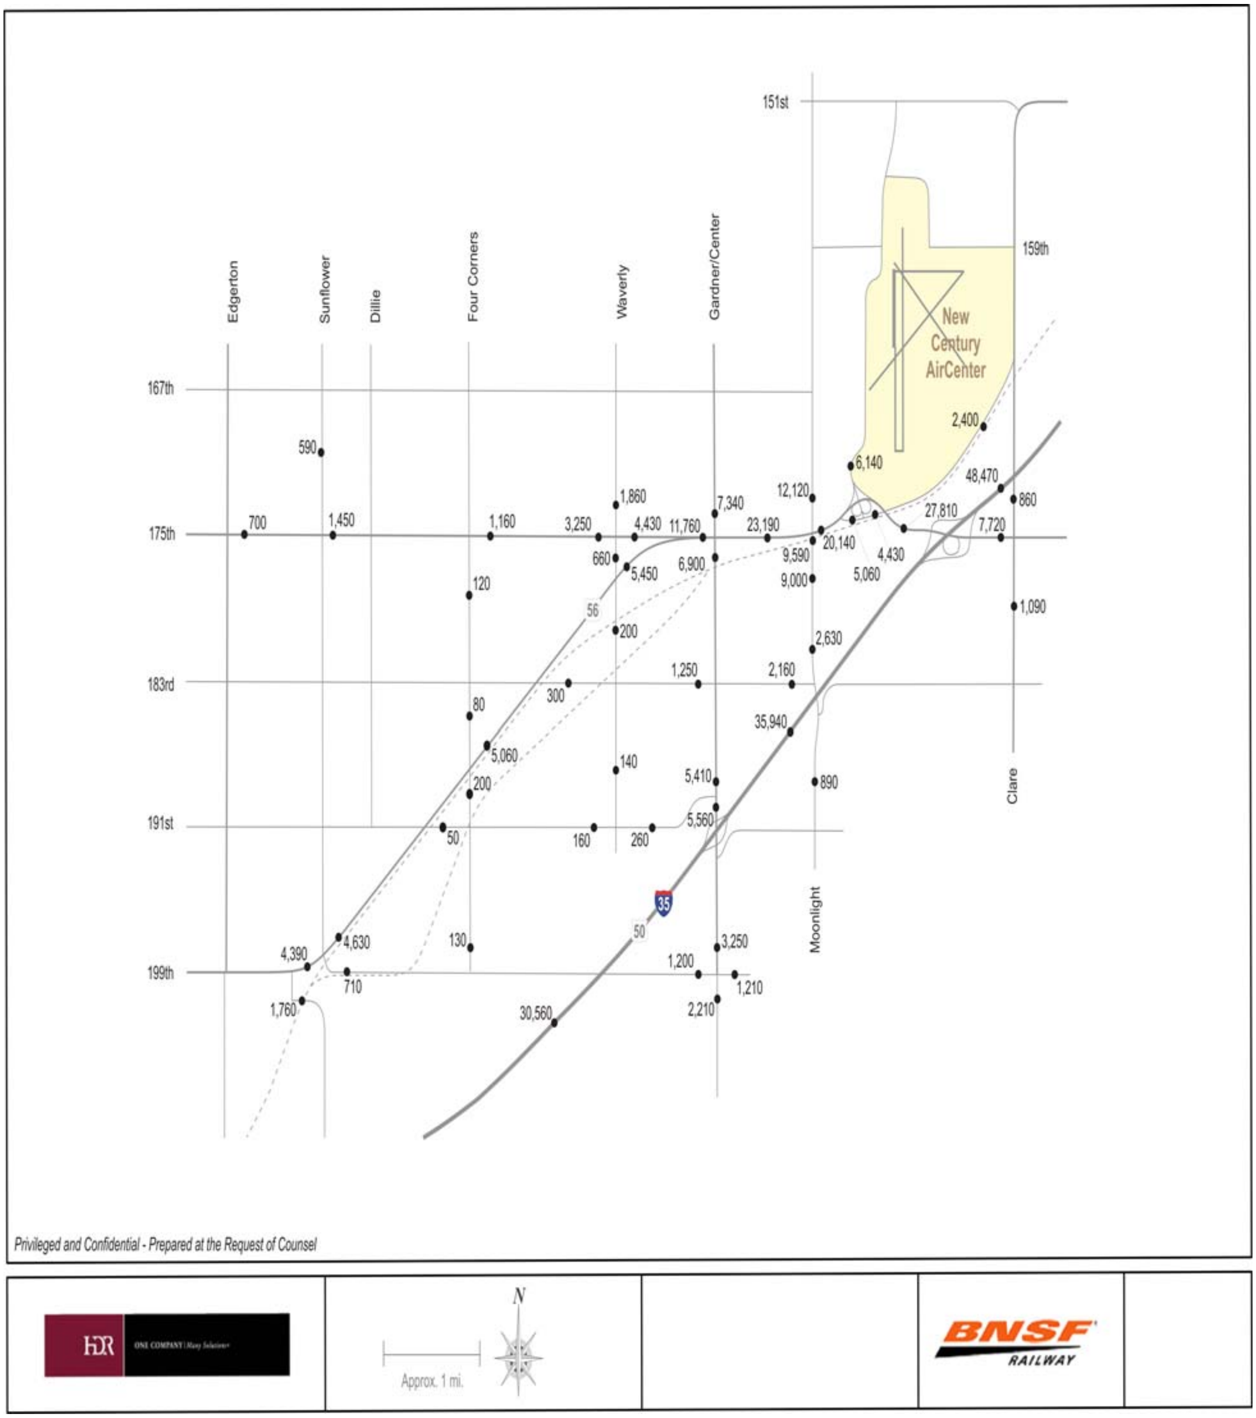


Figure 3-2: 2010 Gardner No Action Peak Hour Turning Movement Volumes

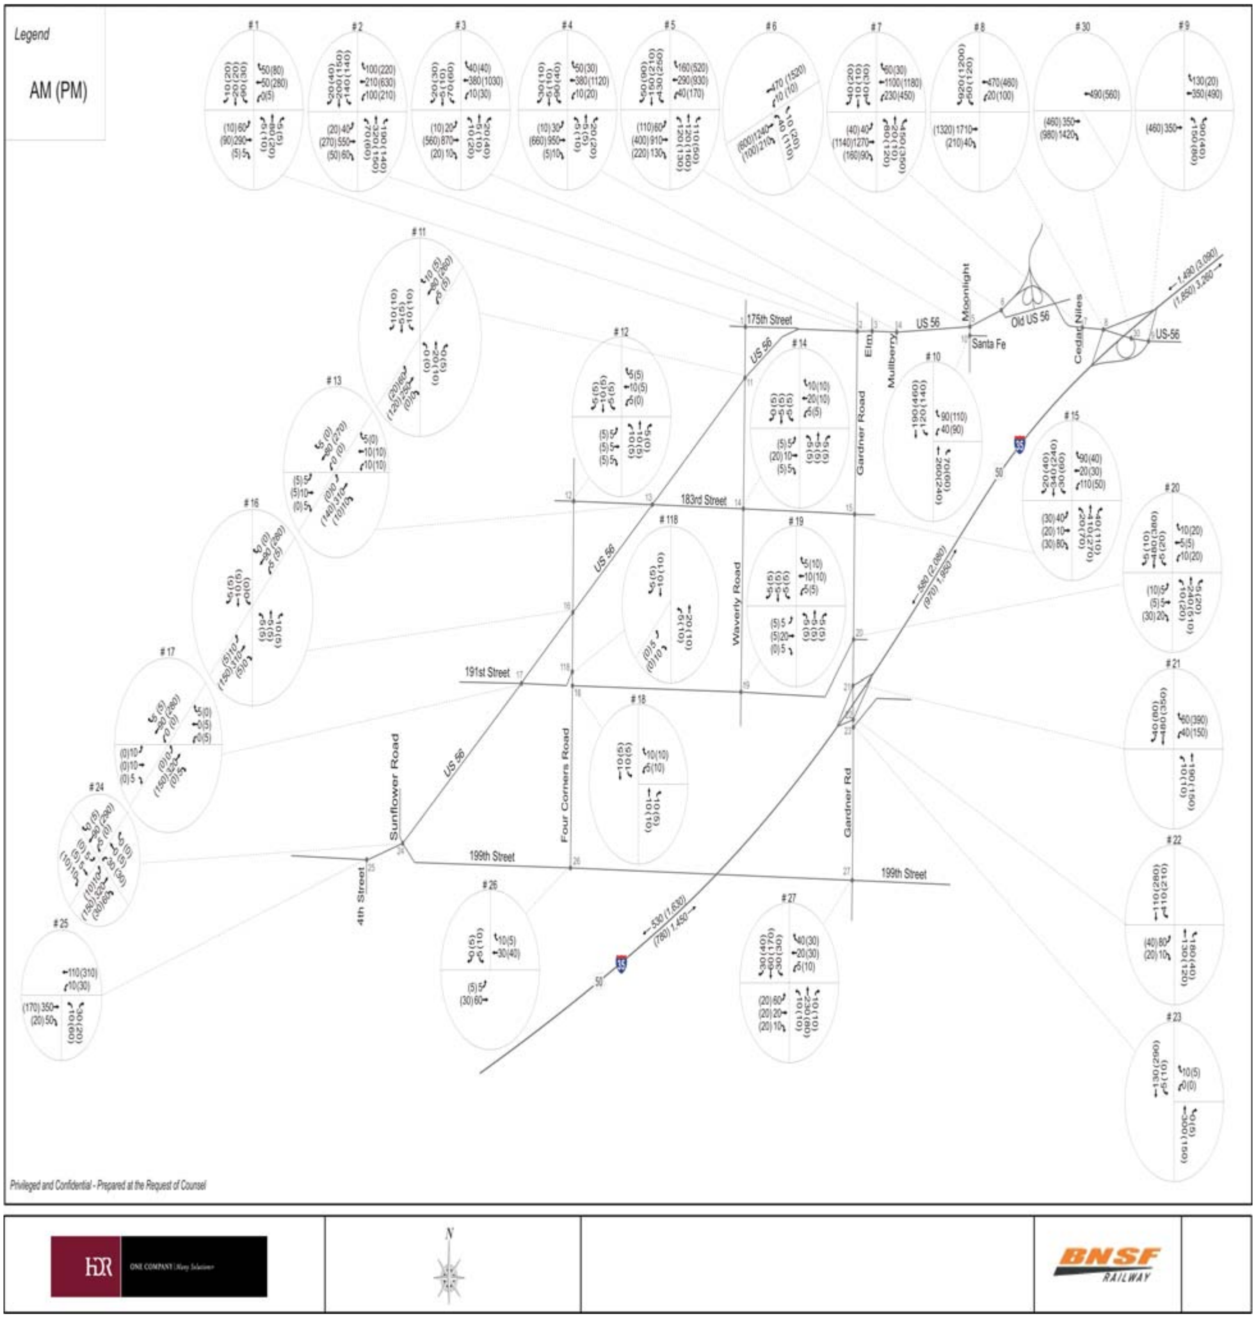

<u>2010 Gardner No Action Intersection Operational Analysis</u>

A total of 28 intersections were examined using the projected 2010 No Action traffic volumes and the assumed 2010 No Action transportation network improvements. The results of this analysis are shown in Table 3-1. (Detailed intersection calculations for all of the Gardner No Action scenarios are included in Appendix E.) In this scenario, four study intersections were forecasted to operate at LOS E or worse during one or both peak hours. These intersections include:

- *Intersection #6 (US 56/Old US 56):* This intersection is an unsignalized 3-leg intersection. The northbound movement is stop-controlled and is expected to operate at LOS F in both the a.m. and p.m. peak hours.
- *Intersection #8 (US 56/I-35 southbound ramps):* The southbound left-turn movement at this intersection is projected to operate at LOS F in the p.m. peak hour. In addition, as traffic grows the southbound right movement can also be expected to experience increased delays due to the need to merge onto US 56.
- *Intersection #9 (US 56/I-35 northbound ramps):* The northbound ramp approach to this intersection is projected to operate below the acceptable LOS threshold during both peak hours.
- *Intersection #15 (183rd Street/Gardner Road):* The westbound left-turn movement at this intersection is projected to operate at LOS E in the a.m. peak period.

Notes:
TWSC – Two-way STOP control, OWSC – One-way STOP control, AWSC – All-way STOP control, LOS – Level of Service.
For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.
Bold indicates a LOS below the acceptable threshold.
[1] Unsignalized in 2010 No Action, Signalized in Improved 2010 No Action.
[2] The southbound right movement is assumed to be free flow.
[3] Improvement due to signal coordination

Given that these four intersections are projected to operate below the acceptable LOS threshold under the No Action scenario, it was assumed that signals would be installed at these locations by mid 2010. Signals have been discussed in recent traffic studies at the first three of these locations (# 6, 8, and 9) and all three of those locations are expected to be near the threshold for warranting signals. Signal warrant studies may be appropriate at all four locations by 2010. The No Action geometry with signals assumed at these locations is referred to as the "Improved No Action" analysis and was used as the baseline for the 2010 impact analysis. With signals at these four locations, all intersections are predicted to operate acceptably in the Improved No Action scenario. This provides a practical baseline that meets the minimum LOS standard, from which to conduct the Proposed Action impact analysis.

<u>2010 Gardner No Action Freeway and Ramp Analysis</u>

The 2010 No Action freeway analysis assumed the forecasted volumes presented in Figure 3-1 and the current mainline and ramp geometry. The resulting operational analysis (for both mainline and ramp junctions) is summarized in Table 3-2. As the table indicates, all locations are forecasted to operate at an acceptable LOS D or better during both peak hours (Detailed freeway and ramp calculations for the Gardner No Action scenarios are provided in Appendix E).

Table 3-2: 2010 Gardner No Action Freeway/Ramp Operational Analysis

3.1.2 2010 Proposed Action

2010 Proposed Action Forecasts

The traffic generated by the Proposed Action in Gardner was estimated based on on-site employment estimates, expected shift-change patterns and opening day lift projections for the Gardner IMF in conjunction with historical data from the existing BNSF Argentine facility. Based on these sources, it was estimated that the Gardner project site would generate approximately 2,900 vpd in 2010, 273 during the a.m. peak hour and 185 during the p.m. peak hour (Table 3-3). The table separates bobtails (unloaded trucks with no chassis) because they are much lighter, and affect traffic operations much less than trucks carrying trailers or containers.

Additional information on site-trip generation is provided in Appendix A.

Table 3-3: 2010 Proposed Action Trip Generation

		AM Peak Hour			PM Peak Hour		
	Daily	in	out	total	in	out	total
Trucks	1,489	32	49	81	57	45	102
Bobtails	1,065	23	35	58	41	32	73
Non-Trucks	343	67	67	134	4	6	10
Total	2,897	122	151	273	102	83	185

Note: Bobtails are not typically measured at existing IMFs.
A conservative estimate was calculated to capture potential bobtail traffic. Actual bobtail trips are likely to be less than what has been projected as trips will be generated by lifts and container staging.

The new auto trips associated with the Proposed Action were distributed to destinations and assigned to the local roadway system in a manner consistent with the local land uses and street network. The truck traffic was distributed based on the results of a shipper survey. These truck trips were assigned based on minimizing travel times; however, it was assumed that truck traffic would be restricted from using 183rd Street as a through street. The traffic distribution assumptions (i.e., trip end locations) for both classes of traffic are provided in Appendix A.

The 2010 Proposed Action ADT and peak-hour forecasts are presented in Figures 3-3 and 3-4. The Proposed Action peak hour truck percentages are illustrated in Appendix C.

Figure 3-3: 2010 Gardner Proposed Action ADTs

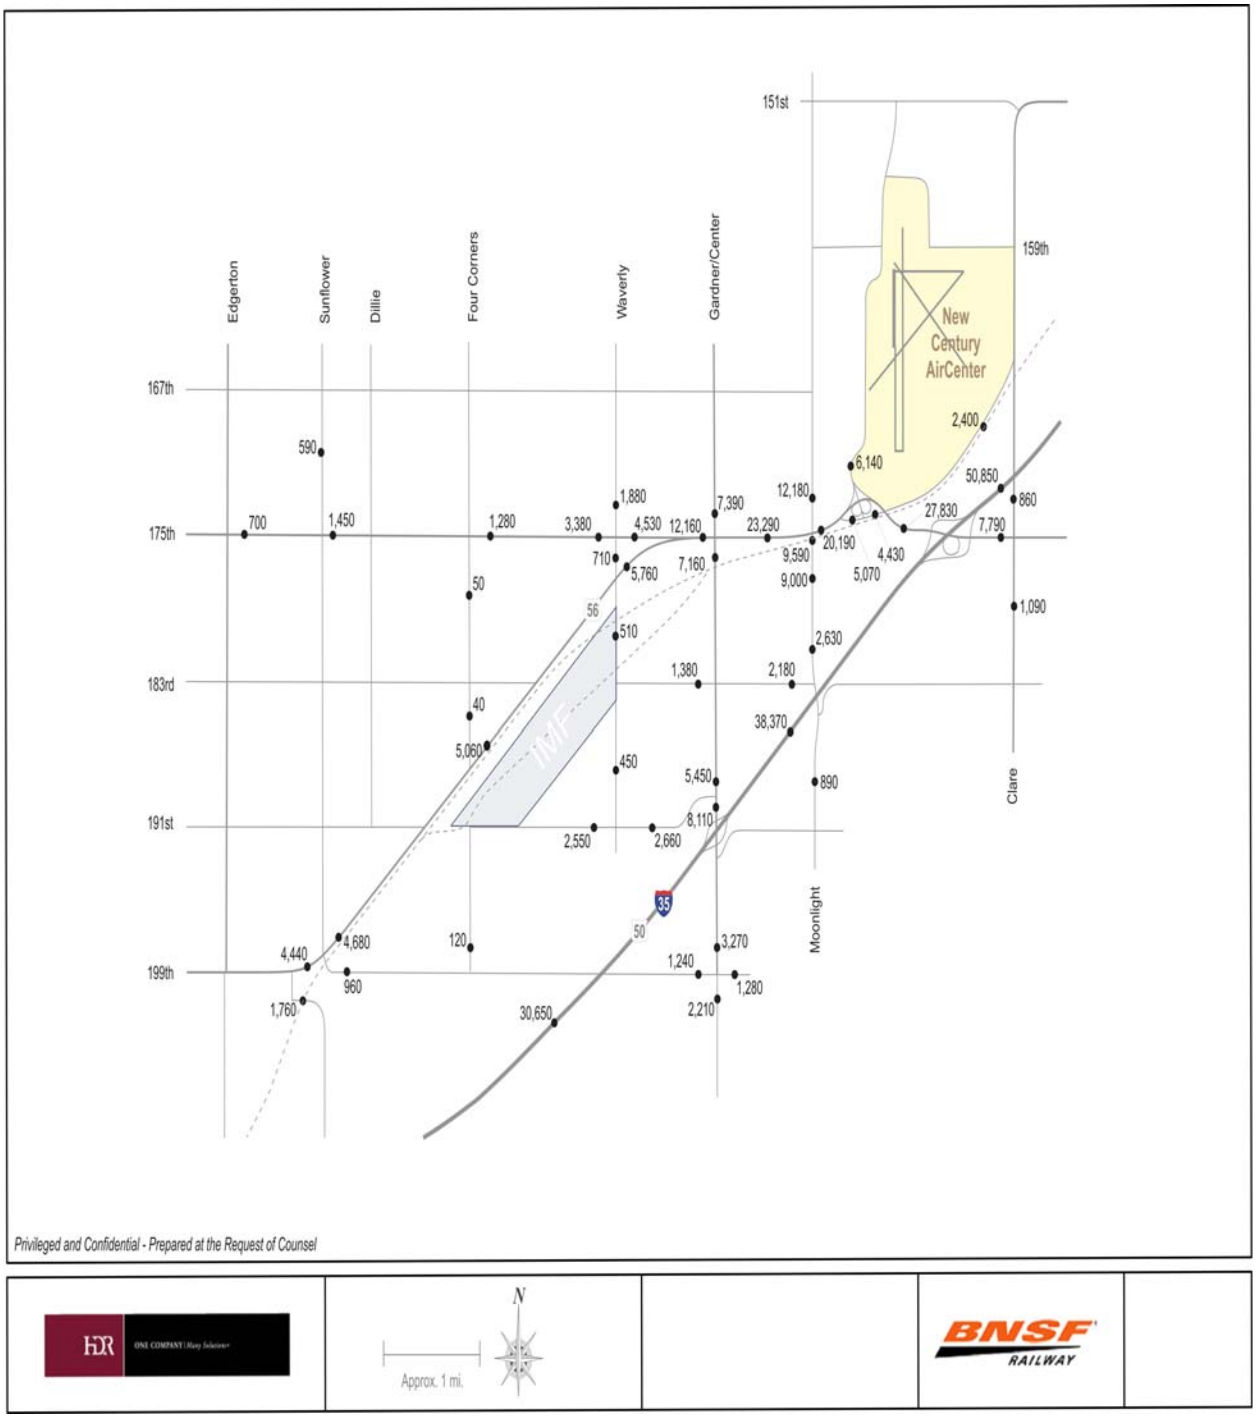

Figure 3-4: 2010 Gardner Proposed Action Turning Movement Volumes

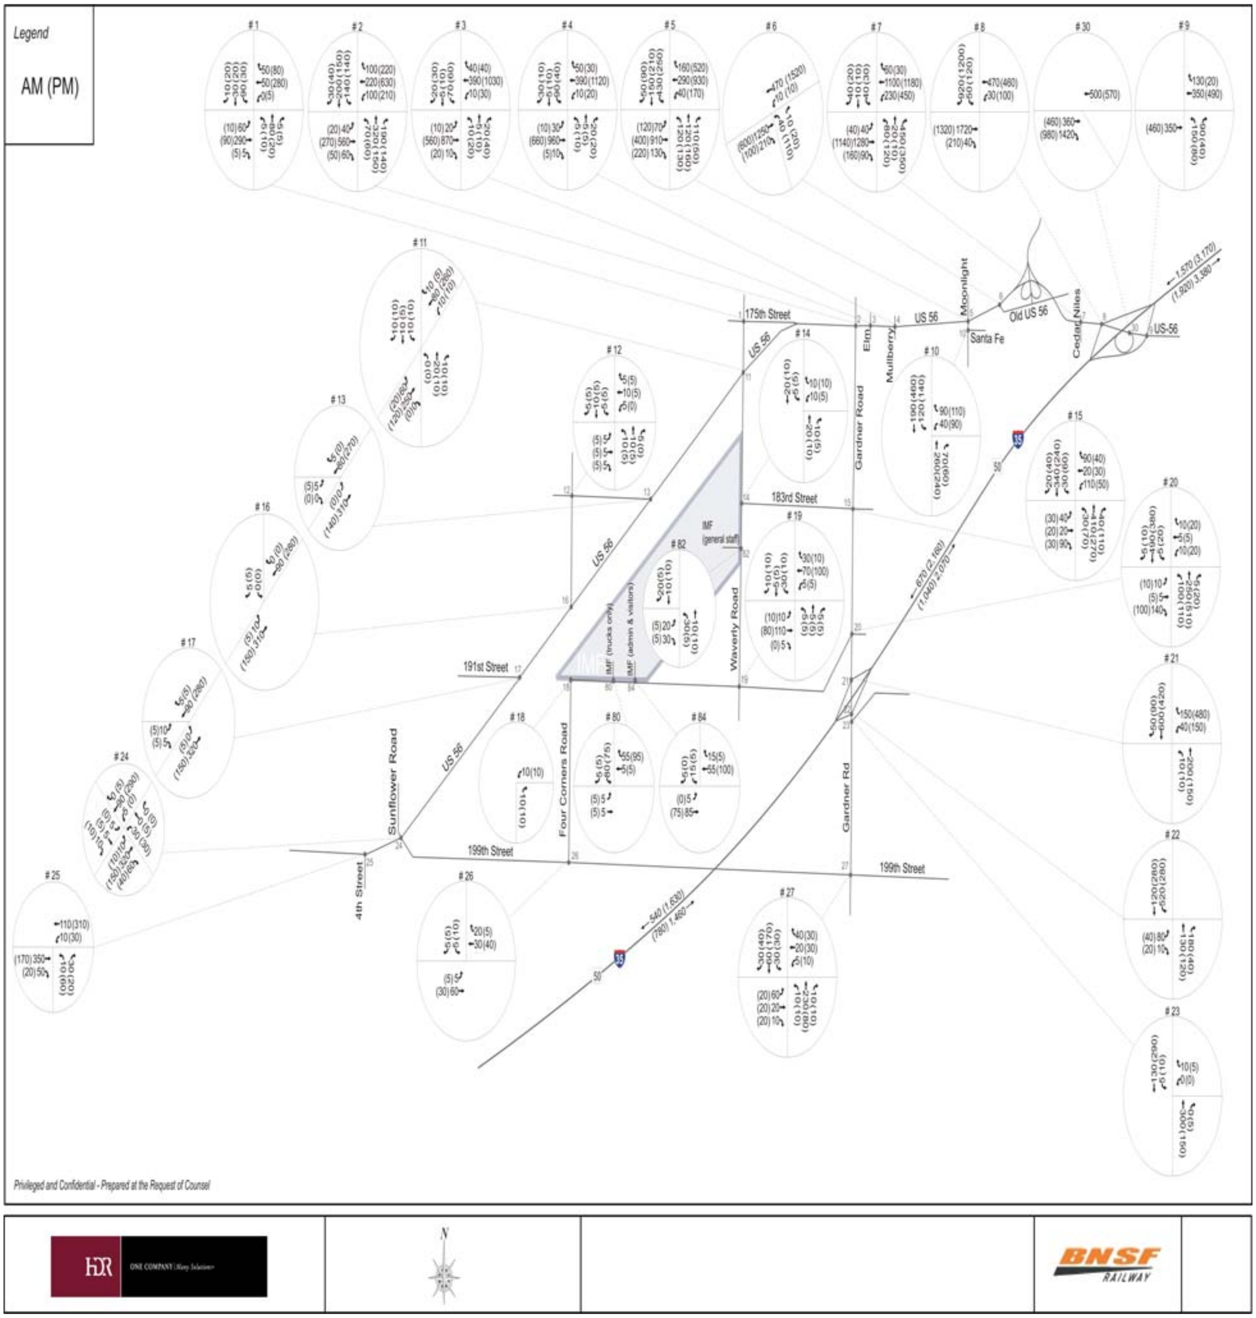

<u>2010 Proposed Action Operations Intersection Analysis</u>

The 2010 Proposed Action operational analysis was conducted based on the 2010 Improved No Action geometry and the 2010 Proposed Action traffic volumes discussed in the previous section. The resulting levels or service for all study locations are discussed in this section.

The intersection operational analysis is summarized in Table 3-4. Intersection #1 was forecasted to drop from LOS C to D, but none of the study intersections were forecasted to operate below the LOS D threshold in the 2010 Proposed Action scenario; therefore, no significant impacts were predicted to occur (Detailed intersection analysis sheets for the Proposed Action and Future Gardner IMF scenarios are presented in Appendix E).

For one and two-way STOP controlled intersections the delay and LOS for the worst approach is shown.

<u>2010 Proposed Action Freeway and Ramp Analysis</u>

The 2010 Proposed Action freeway and ramp analysis is summarized in Table 3-5. Again, none of the freeway segments or ramp junctions was forecasted to operate below LOS D in this scenario. Therefore, the Proposed Action would result in only minor impacts to freeway and ramp operations in 2010, its first year of operations. Detailed freeway facility operational analysis sheets for the Proposed Action and Future Gardner IMF Operations scenarios are presented in Appendix E.

Table 3-5: 2010 Proposed Action Freeway/Ramp Operational Analysis

3.2 Indirect Effects - Future Gardner IMF Operations

3.2.1 2015 Gardner No Action

<u>2015 Gardner No Action Forecast Volumes</u>

The 2015 Gardner No Action scenario is a near-term scenario for comparing No Action conditions to those from the Proposed Action five years after opening day. It assumes modest near-term traffic growth consistent with historical growth in the area. Based on KDOT count data, and consistent with the recently completed I-35 Gardner BIA Study, a growth rate of 2.8 percent per year was assumed for intersections and a growth rate of approximately 3.2 percent per year was assumed for the I-35 mainline. These growth rates were applied to the existing (2008) volumes.

The resulting 2015 No Action ADT volumes and peak-hour turning movement volumes are illustrated in Figures 3-5 and 3-6 and the peak hour truck percentages are illustrated in Appendix C. As shown in these figures, traffic is expected to continue to increase on the major study area roadways such as I-35, US 56, and Gardner Road even without construction of the Proposed Action and any indirect effects of the Proposed Action.

<u>2015 Gardner No Action Geometry Assumptions</u>

The No Action 2015 roadway network geometry was assumed to be similar to the 2010 Improved No Action geometry with the exception that it was assumed that all-way stop control would be implemented at the intersection of Waverly Road and 175th Street (Intersection #1), an improvement that was considered necessary to provide an adequate baseline LOS. KDOT is currently pursuing the development of a new interchange on I-35 between Sunflower Road and Gardner Road. It was assumed that the new interchange would not be operational until at least 2015. Therefore, to be conservative, the 2015 analysis did not include the new interchange and, as a result, presents the traffic conditions before the new interchange would open.

Figure 3-5: 2015 Gardner No Action ADTs

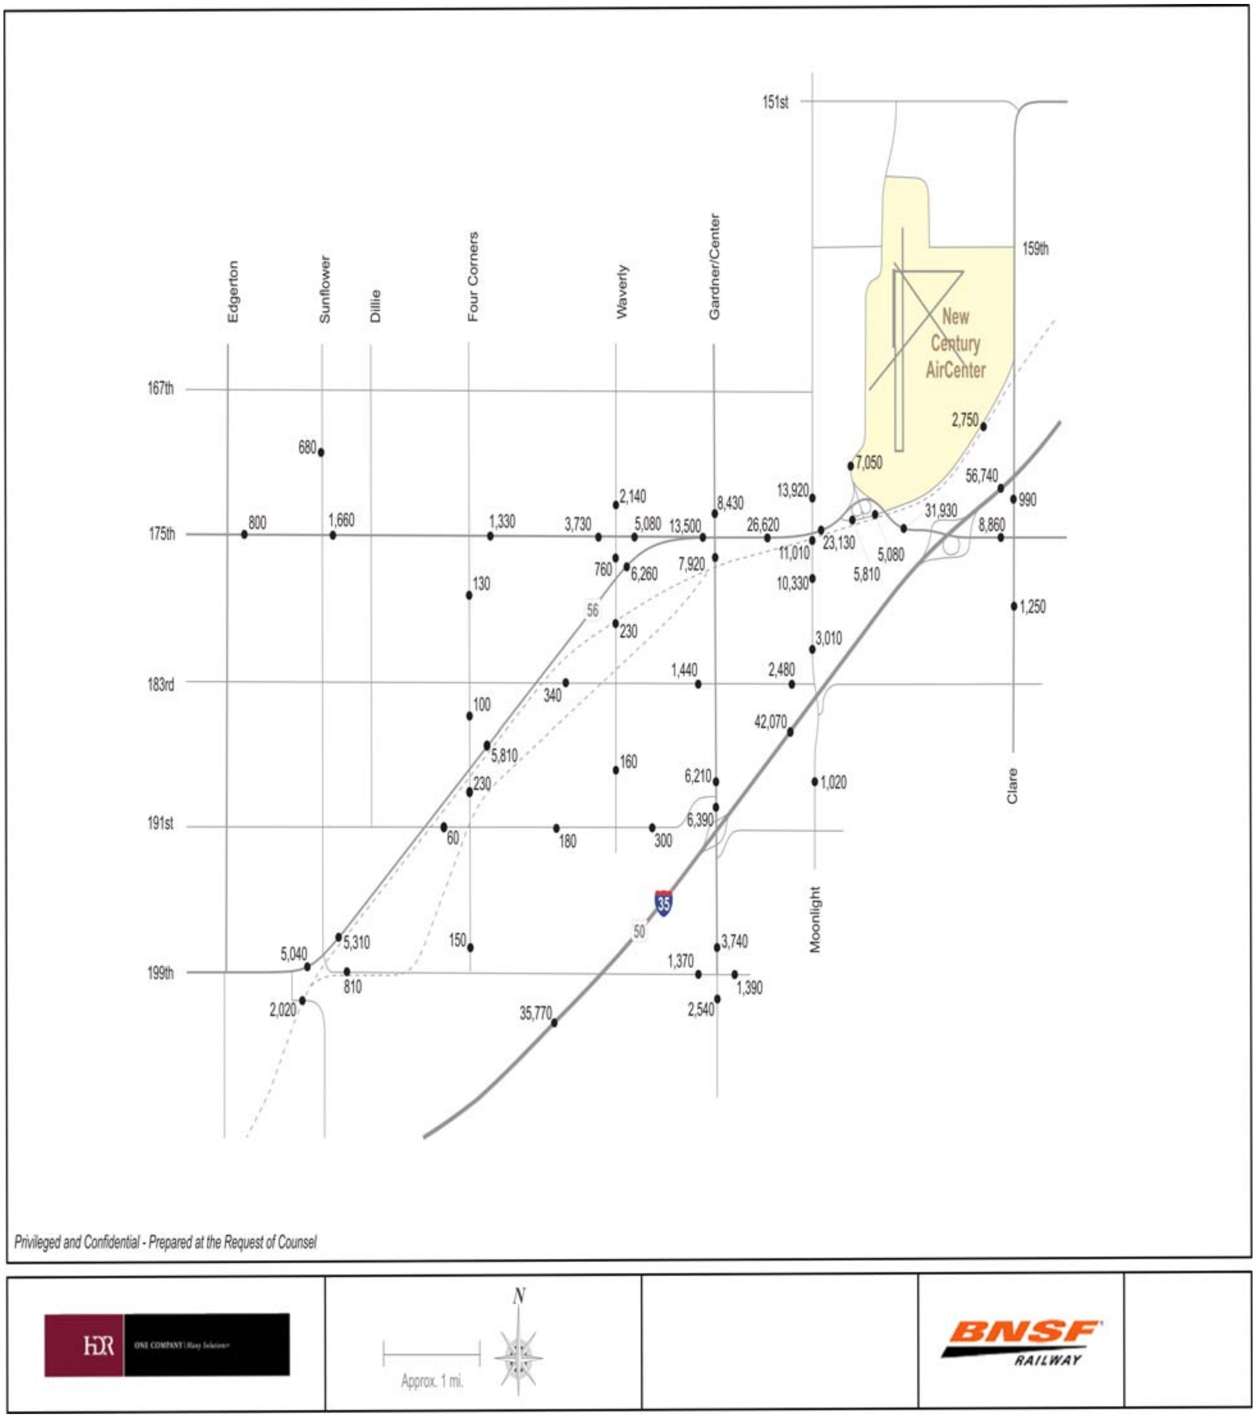

Figure 3-6: 2015 Gardner No Action Turning Movement Volumes

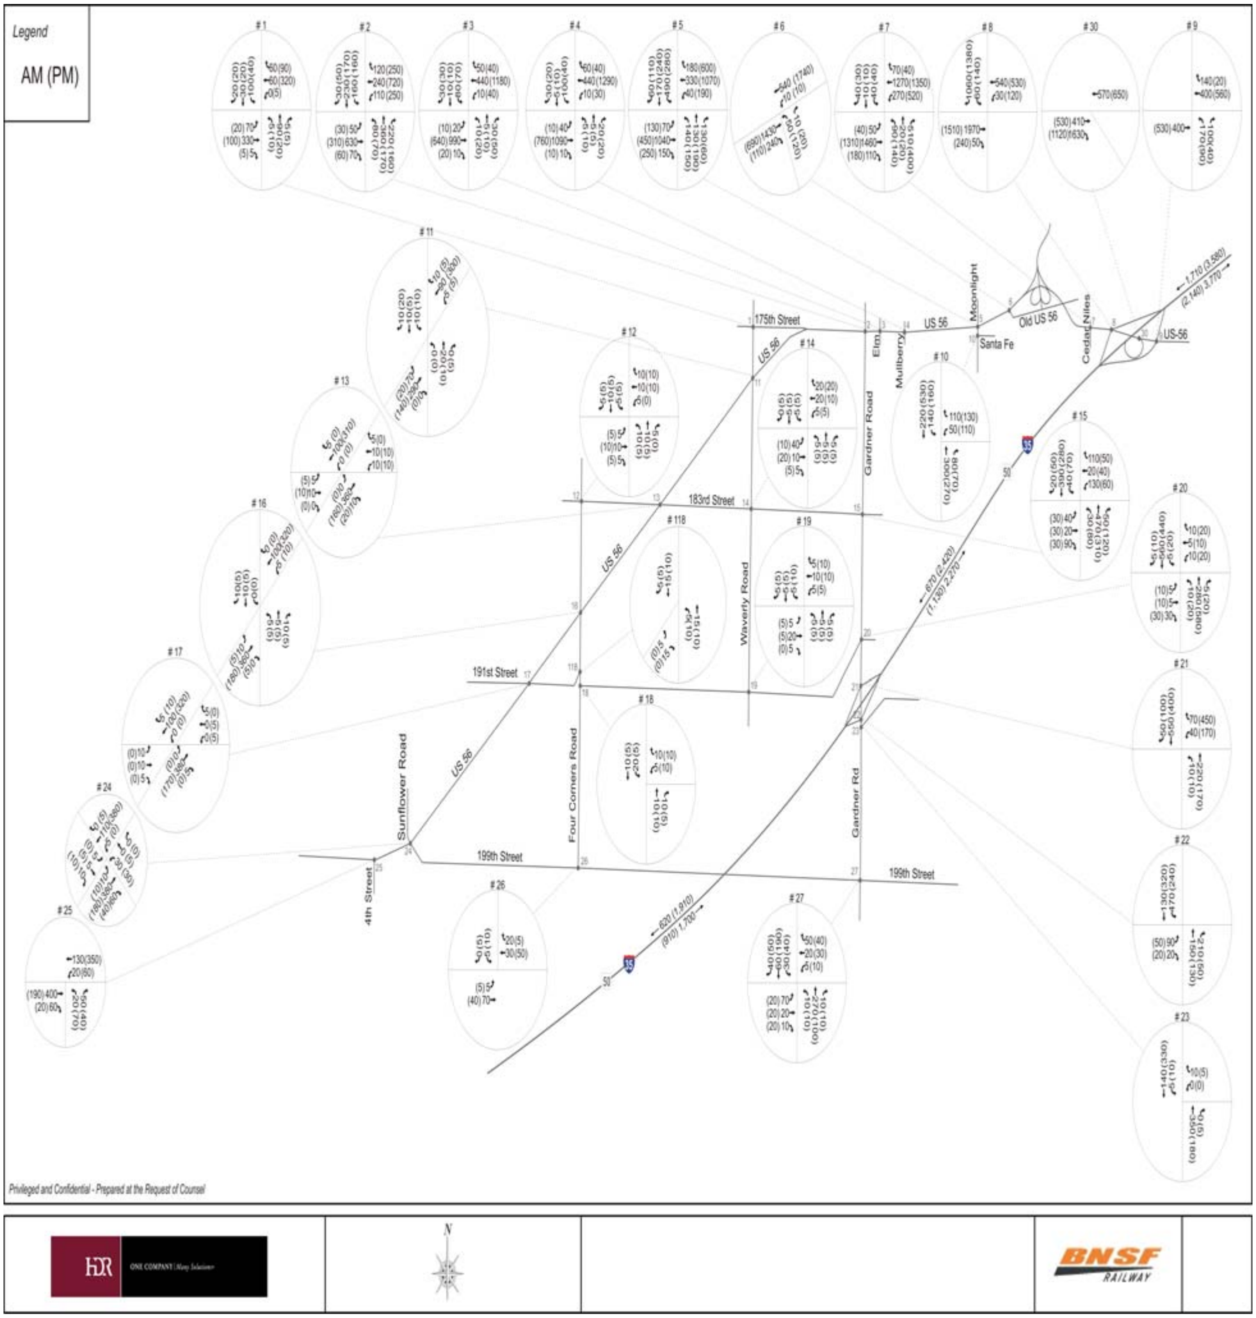

2015 Gardner No Action Operations Intersection Analysis

The results of the 2015 No Action operations intersection analysis are shown in Table 3-6. Given the assumed geometry described in the previous section, none of the intersections in this scenario are forecasted to operate below LOS D during the a.m. or p.m. peak periods. Therefore, only minor impacts are predicted for intersections in 2015 as a result of the No Action Alternative, assuming the previously discussed intersection improvements.

Table 3-6: 2015 Gardner No Action Study Intersection Analysis

Notes: TWSC – Two-way STOP control, OWSC – One-way STOP control, AWSC – All-way STOP control, LOS – Level of Service.
For one and two-way STOP controlled intersections the delay and LOS for the worst approach is shown.
[1] This LOS reflects four-way stop control. With the existing two-way stop control, the LOS would be E (38.3 sec/veh) and C (16 sec/veh) in the am and pm peaks, respectively.

2015 Gardner No Action Freeway and Ramp Analysis

The 2015 No Action freeway analysis is summarized in Table 3-7. With the additional future traffic, LOS on these facilities is forecasted to decrease from the existing primarily A/B levels, to C/D levels in a few cases. In particular, the northbound volume north of US 56 is 0.5 below the LOS E density threshold of 35 passenger cars per lane per mile. There are, however, no locations forecasted to operate at LOS E or worse in this scenario; therefore only minor impacts would occur to freeway facilities and ramps as a result from the 2015 No Action Alternative.

Table 3-7: 2015 Gardner No Action Freeway/Ramp Operational Analysis

3.2.2 2015 Gardner IMF Operations

<u>2015 Gardner IMF Operations Forecasts</u>

The 2015 trip generation and distribution process for the Gardner IMF was identical to that used for the 2010 scenario, only with a higher annual lift count (495,000 in 2015 as compared to 415,000 in 2010). This higher lift count resulted in more trips - a total of nearly 3,500 vpd, including 335 during the a.m. peak hour and 222 during the p.m. peak hour. Table 3-8 summarizes the 2015 trip generation assumptions. Additional information on the daily and peak hour trip generation is provided in Appendix A.

Table 3-8: 2015 Gardner IMF Operations Trip Generation

		AM Peak Hour			PM Peak Hour		
	Daily	in	out	total	in	out	total
Trucks	1,776	39	58	97	68	54	122
Bobtails	1,270	28	42	70	49	38	87
Non-Trucks	430	84	84	168	5	8	13
Total	3,476	151	184	335	122	100	222

Note: Bobtails are not typically measured at existing IMFs. A conservative estimate was calculated to capture potential bobtail traffic. Actual bobtail trips are likely to be less than what has been projected as trips will be generated by lifts and container staging.

The 2015 Gardner IMF Operations ADT and peak-hour forecasts are shown in Figures 3-7 and 3-8. The peak hour truck percentages are illustrated in Appendix C. The operational analysis for this scenario was conducted based on the 2015 Improved No Action geometry and the 2015 Gardner IMF Operations traffic volumes. The resulting levels or service for all study locations are discussed in the following sections.

Figure 3-7: 2015 Gardner IMF Operations ADTs

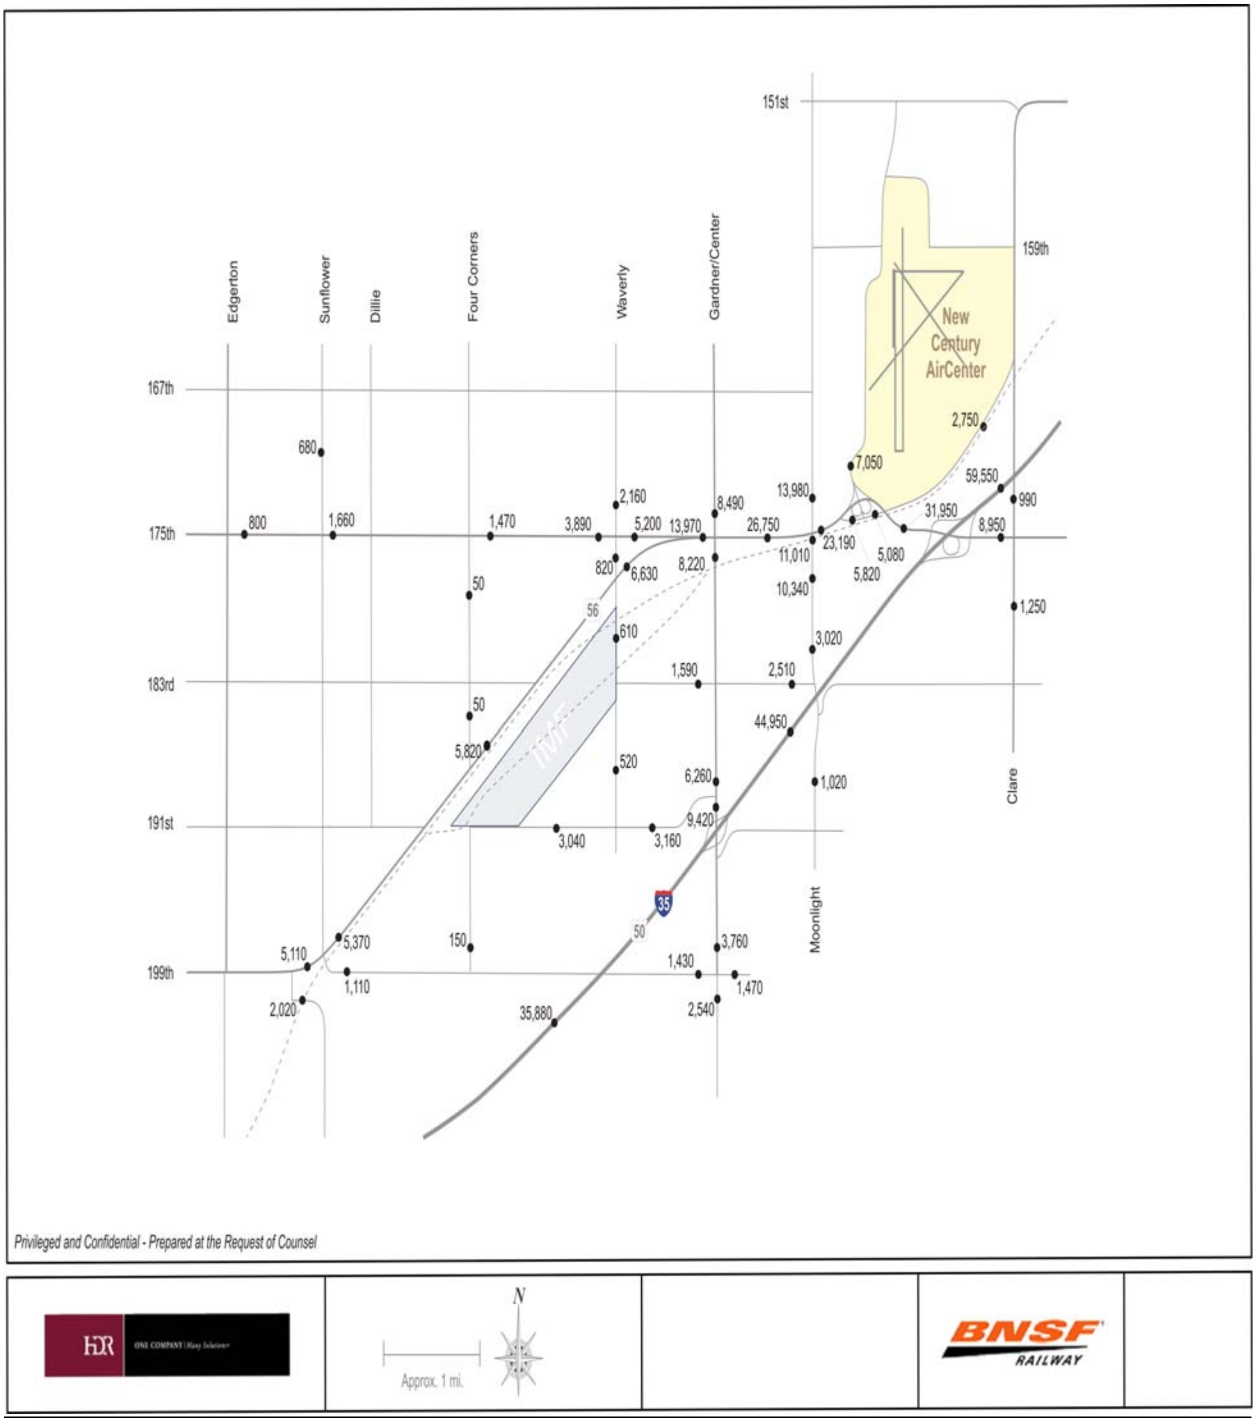

Figure 3-8: 2015 Future Gardner IMF Operations Turning Movement Volumes

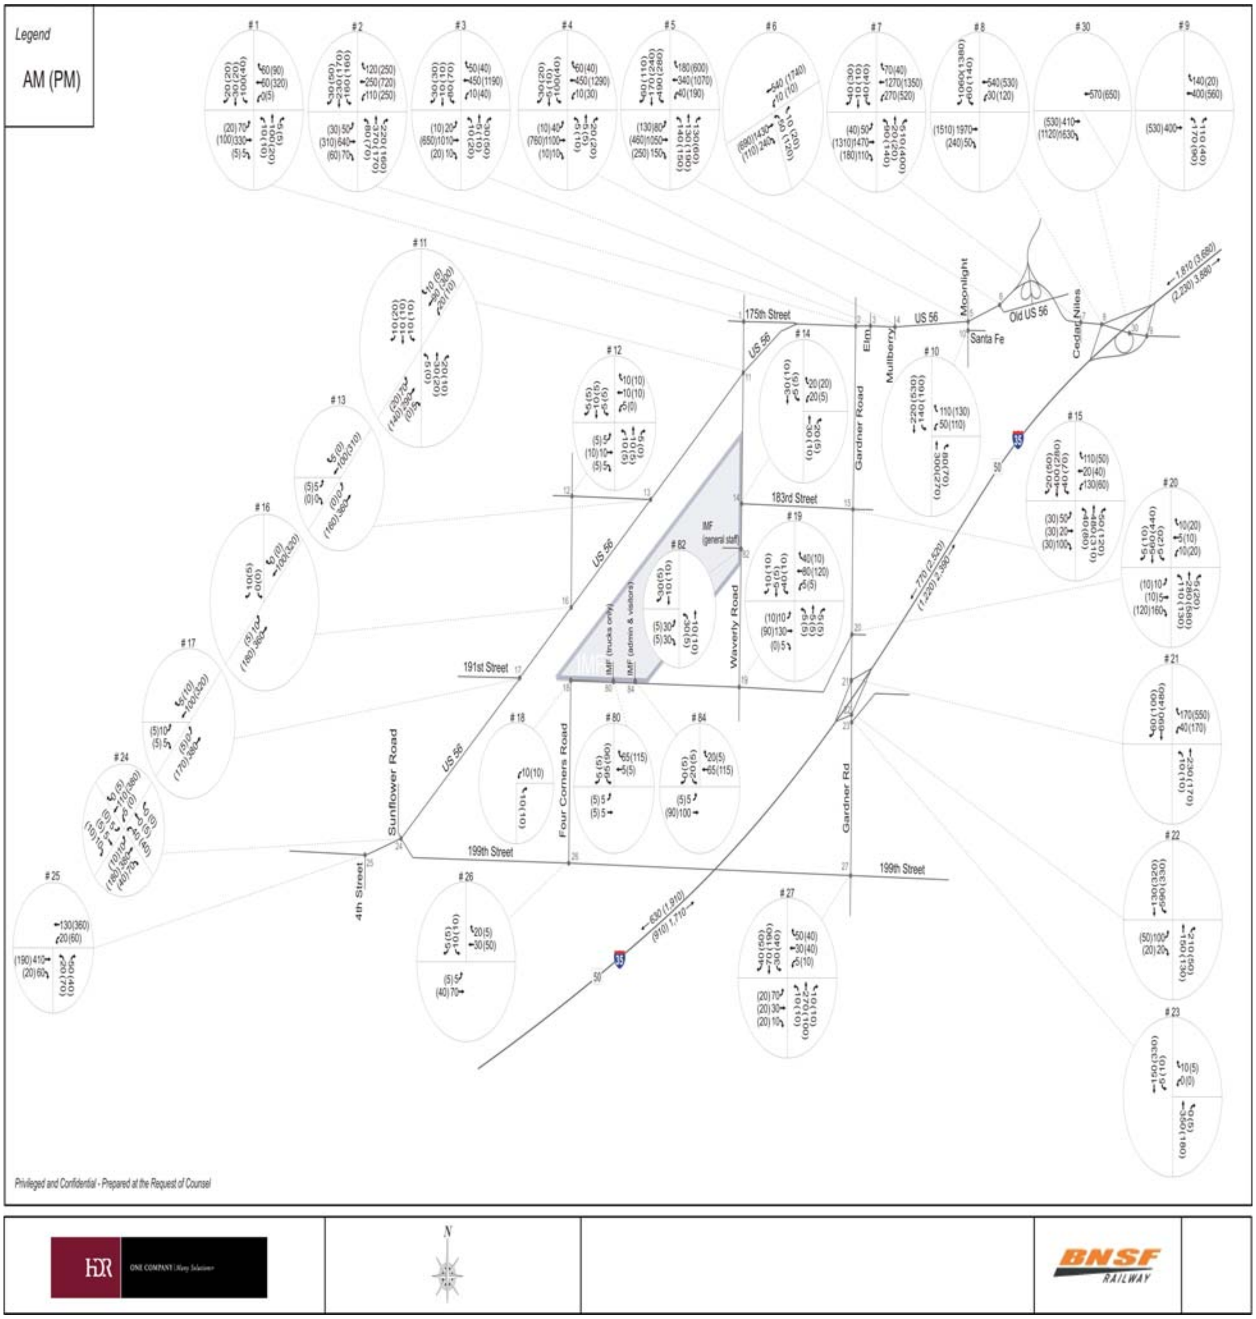

2015 Gardner IMF Operations Intersection Analysis

The intersection operational analysis is summarized in Table 3-9. One intersection (Intersection #22, I-35 Northbound Ramps/Gardner Road) was forecasted to drop to LOS D, but none of the study intersections would operate below the LOS D threshold in the 2015 Gardner IMF Operations scenario. Therefore, only minor impacts are predicted in 2015 to local intersections as a result of the Proposed Action.

Bold indicates a LOS below the acceptable threshold.

2015 Gardner IMF Operations Freeway and Ramp Analysis

The 2015 Gardner IMF Operations freeway and ramp analysis is summarized in Table 3-10. One freeway segment that was forecasted to operate at LOS D (near the LOS E boundary) under No Action conditions is shown to just cross the LOS E threshold under this scenario:

- *I-35 Northbound, US 56 to 151st Street:* This segment is projected to operate at LOS E during the a.m. peak hour. Widening I-35 to carry three lanes in each direction is included in MARC's Long-Range Transportation Plan (LRTP) for construction sometime between 2011 and 2020, and would improve the LOS to acceptable levels.

A related LOS issue also is forecasted to occur on the US 56 eastbound on-loop to US 56: the LOS drops from D (near the E threshold) to E (just over the threshold). Again, the programmed improvements in MARC's LRTP should improve this LOS to acceptable levels.

In summary, although the analysis identified two LOS issues, both would be anticipated to be addressed by planned improvements in the fairly near term. If for some reason, the planned improvements to I-35 do not follow what is currently outlined in the LRTP, the 2015 traffic volumes would be near the LOS D/E threshold. Only minimal traffic diversion to the local and regional arterial street system in 2015 would be expected.

3.2.3 2030 Gardner No Action

2030 Gardner No Action Forecast Volumes

The 2030 Gardner No Action scenario is a long-term scenario for comparing No Action and Proposed Action plus the associated indirect effects conditions based on a 20-year time horizon from opening year. The forecasts developed for this scenario were developed using the OTM, adjusted as necessary to refine network and land use assumptions. This model takes into account both long-term land use projections as well as future roadway improvements that are expected to be in place by the horizon year of 2030. The assumptions used in this analysis were developed through a consensus process with appropriate federal, state, and local agencies. The assumptions and the forecasting process are presented in detail in Appendix A. It was assumed a new I-35 interchange would be available by 2030 between Gardner Road and Sunflower Road. For purposes of this analysis, the interchange was assumed to be located near 199th Street and Waverly Road and Waverly Road would be extended south to 199th Street. A break-in-access study has been prepared and KDOT is currently evaluating possible new interchange locations and preparing NEPA documentation.

The resulting 2030 No Action ADT volumes and peak-hour turning movement volumes are illustrated in Figures 3-9 and 3-10. Peak hour truck percentages are illustrated in Appendix C. As these are long-term forecasts, taking into account both new land uses and new highway improvements, the changes from 2015 to 2030 are considerable in some areas. For example, traffic volumes are projected to increase appreciably on US 56 (in the eastern portion of the study area) and I-35. Volumes at both the I-35/US 56 and I-35/Gardner Road interchanges also forecasted to increase appreciably. Due to the assumption of a new interchange at Waverly, traffic volumes on US 56 between Waverly Road and Sunflower Road are actually forecasted to decrease, while traffic volumes on Waverly Road and 199th Street are projected to increase. Some specific highlights in comparing existing and 2030 ADTs:

- Daily volumes on I-35 are forecasted to roughly double, from a current 28,000-46,000 vpd (vpd) range to a 56,000-96,000 range.
- Daily volumes on US 56 between Gardner Road/Center Street and I-35 are forecasted to increase from an existing 19,000-26,000 to a 33,000-43,000 vpd range. East of I-35, volumes are forecasted to jump from 7,300 to 33,000 vpd.
- Daily volumes on Gardner Road/Center Street are expected to increase from a current 5,000-7,000 vpd range to a 21, 000-28,000 range.
- 199th Street is expected to increase from current volumes on the order of 1,000 vpd to volumes ranging from 8,000 to 16,000 vpd.

Similar increases were forecasted during the a.m. and p.m. peak hours.

<u>2030 Gardner No Action Geometry Assumptions</u>
The No Action 2030 roadway network geometry includes a number of assumed enhancements to attempt to provide sufficient capacity for the projected 2030 No Action traffic. Figure 3-11 illustrates the assumed geometry and control for the study intersections.

The model includes many other assumptions regarding future improvements for the entire area covered by the model. These future improvements were assumed to be consistent with agency plans and were not changed as part of this project.

Figure 3-9: 2030 Gardner No Action ADTs

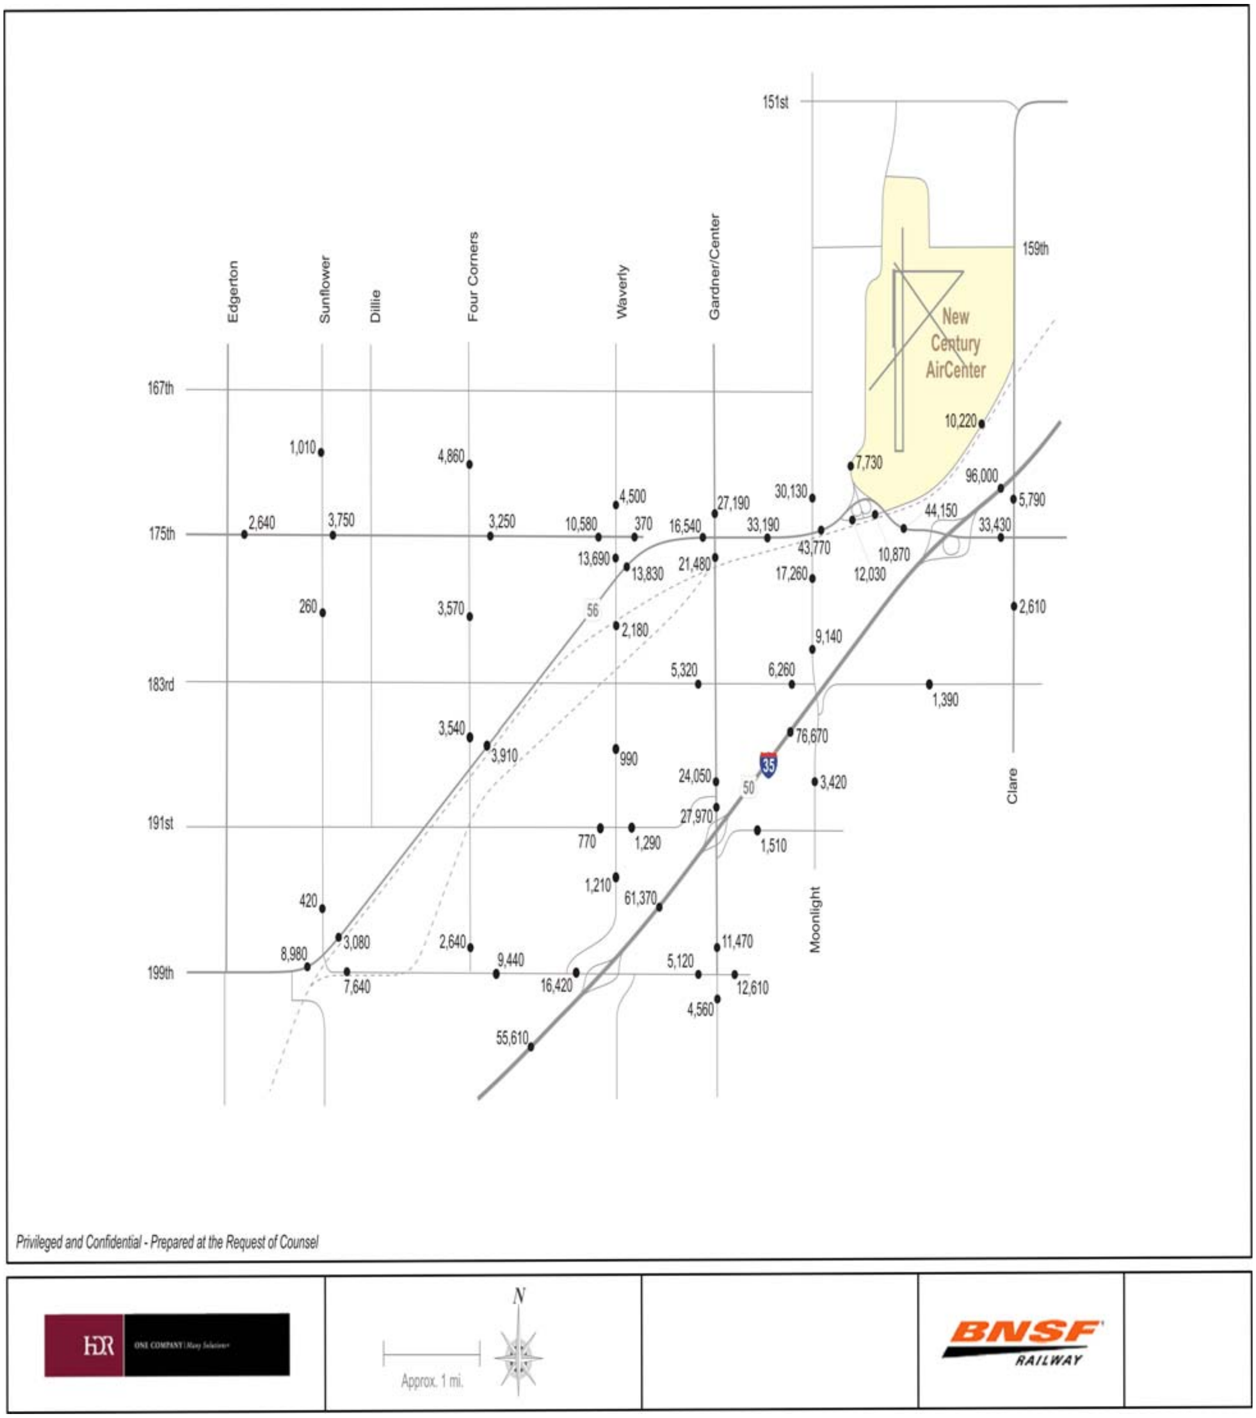

Figure 3-10: 2030 Gardner No Action Turning Movement Volumes

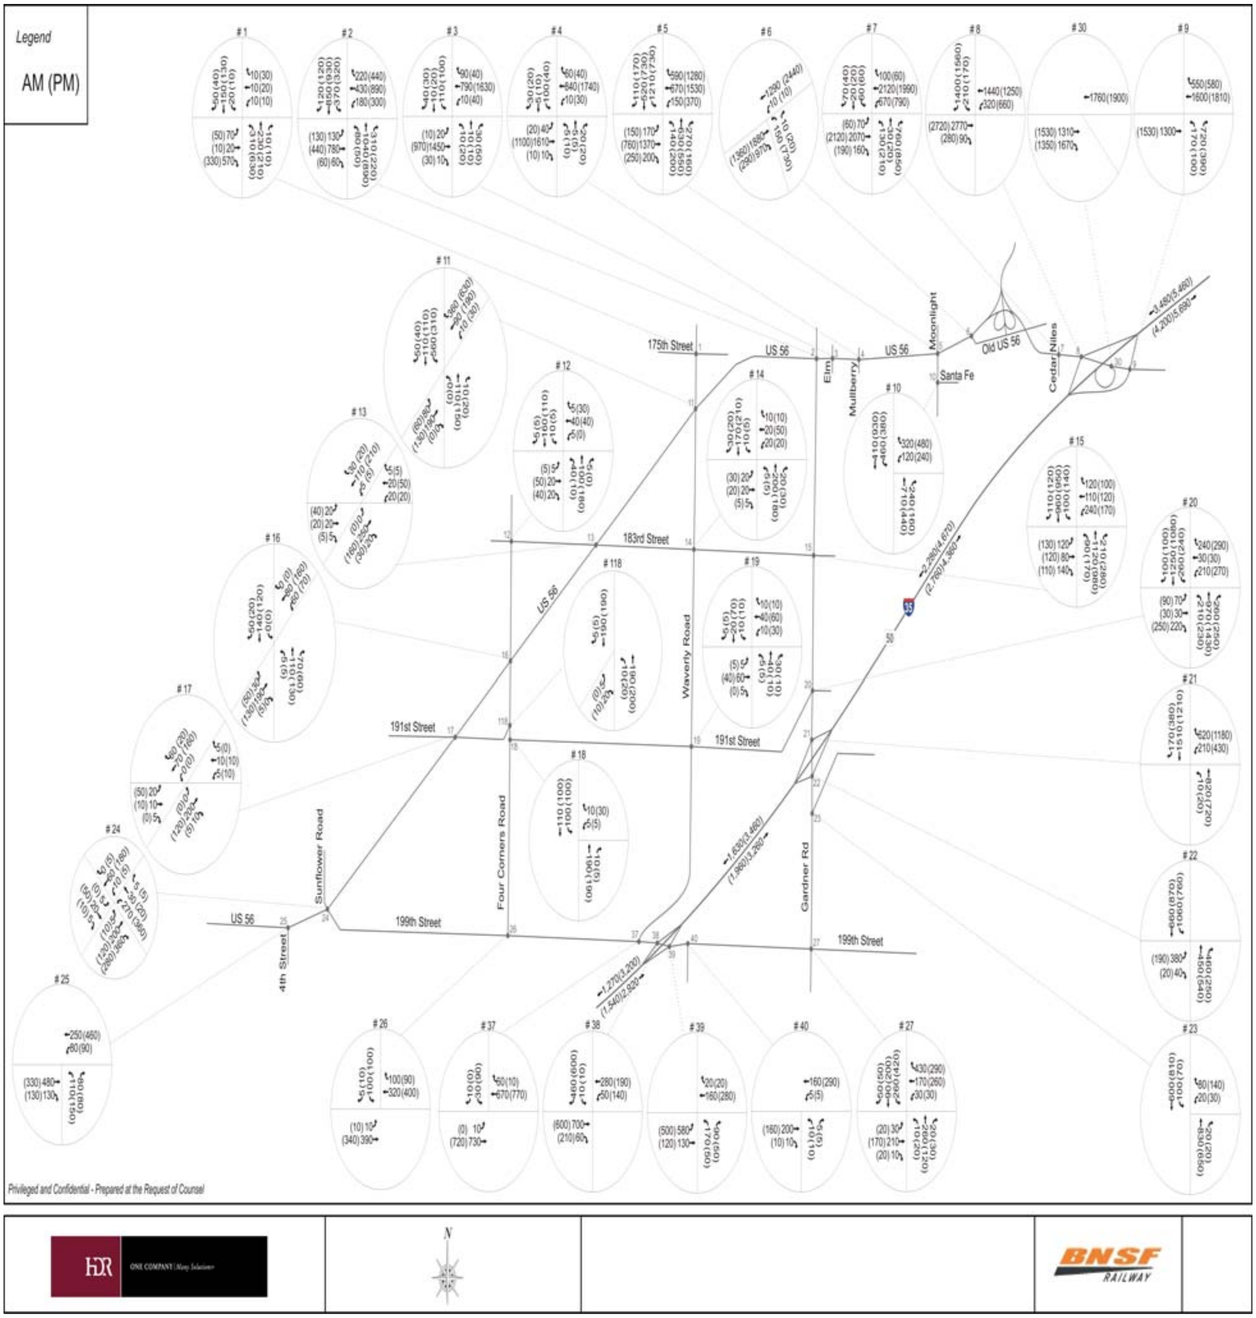

Figure 3-11: 2030 Gardner No Action Lane Configuration and Traffic Control

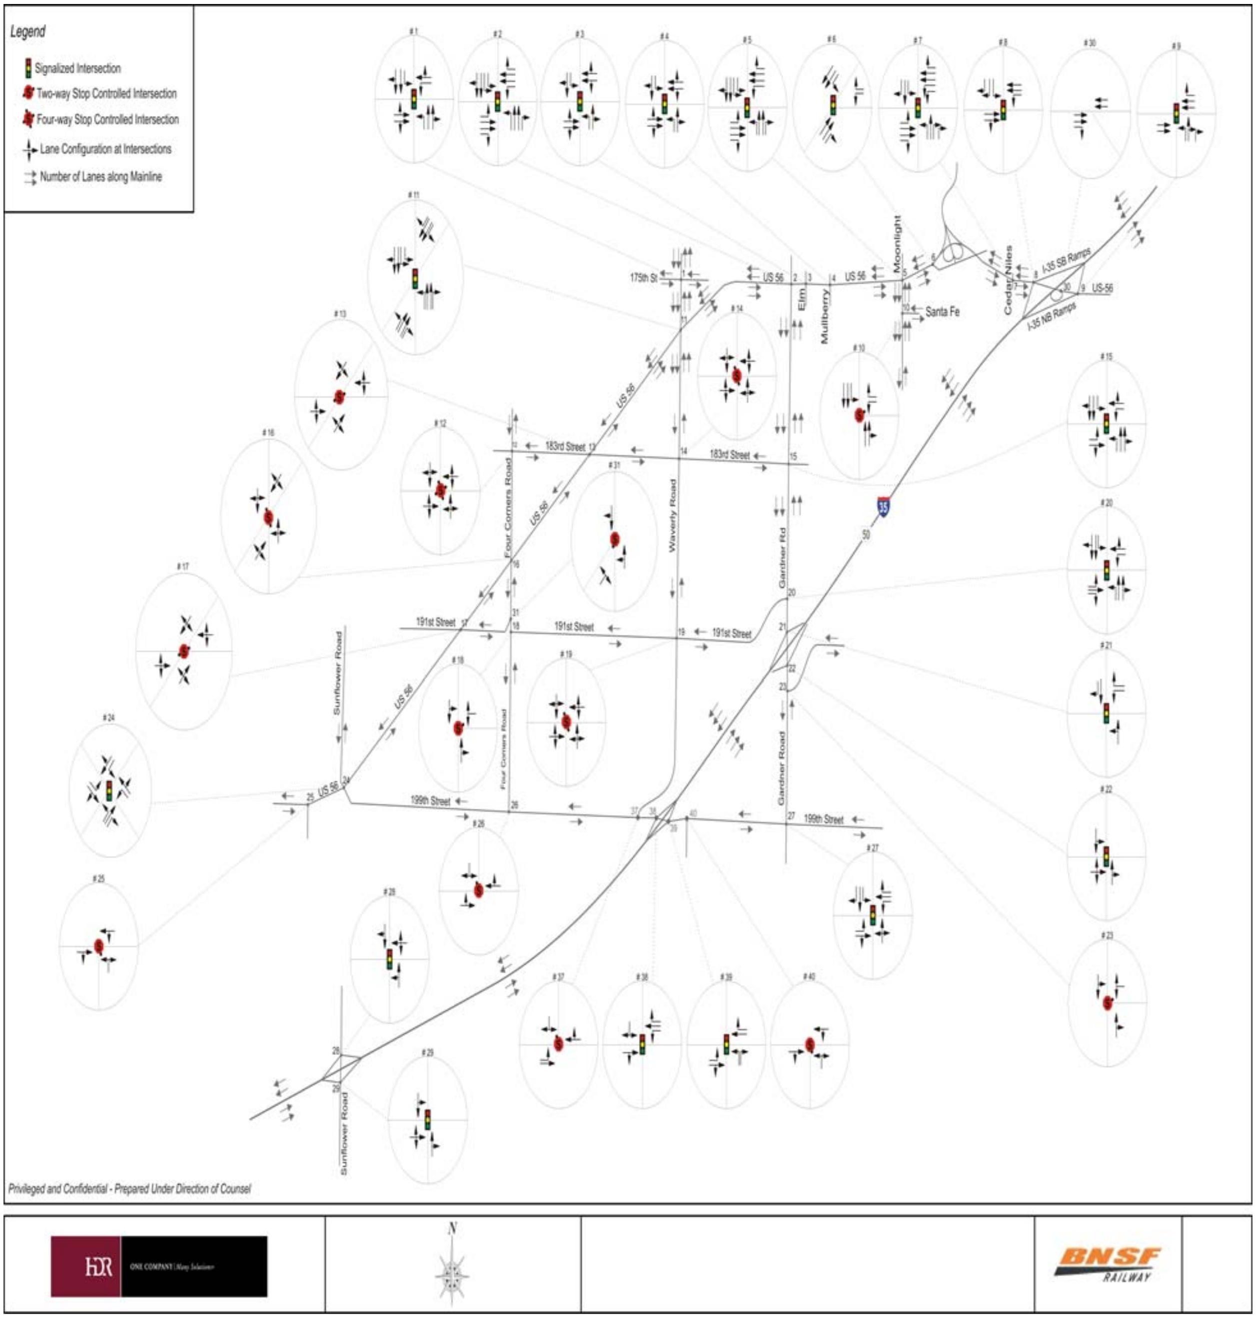

2030 Gardner No Action Intersection Analysis

The results of the 2030 No Action intersection analysis are shown in Table 3-11. As the table indicates, several study intersections are forecasted to operate at LOS E or worse under this scenario during one or both peak hours.

Notes: TWSC – Two-way STOP control, OWSC – One-way STOP control, AWSC – All-way STOP control, LOS – Level of Service.
Bold indicates a LOS below the acceptable threshold.
For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.
[1] Unimproved condition is unsignalized.

- *Intersections #5 through #8 (US 56 from Moonlight Road to I-35 southbound ramps):* All four of these study intersections are projected to operate at LOS E or F during the a.m. and p.m. peak hours. The primary factor affecting operations at these intersections is heavy forecasted traffic on US 56 (peaking in the eastbound direction in the morning and the westbound direction during the evening). The basic conclusion that can be drawn from these results is that US 56 would require three through lanes in each direction from I-35 to at least Moonlight Road under this scenario (No Action Alternative). Additionally, it may be that Moonlight Road in particular, may need future attention for vehicles approaching US 56 from the south, as queuing in the vicinity of the railroad tracks will likely continue to increase.

- *Intersections #21 and #22 (I-35/Gardner Road interchange):* Both of the ramp intersections are forecasted to operate at LOS F during both peak hours, with volumes far exceeding the improved capacities assumed for the No Action Alternative in 2030. These results suggest that the interchange would need to be reconstructed to provide a wider bridge (with perhaps a 7-lane cross-section: two through lanes in each direction, two southbound left-turn lanes, and one northbound left-turn lane), and widened off-ramps (likely four lanes on the southbound off-ramp approach and three lanes on the northbound off-ramp approach). Further, the southbound off-ramp would likely need to be a two-lane exit from I-35.

- *Intersection #23 (Gardner Road/191st Street south):* The stop-controlled westbound (191st Street) approach to this unsignalized intersection is forecasted to operate at LOS F during both peak hours. Forecasted commercial, residential, and industrial growth on Gardner Road south of the intersection would result in heavy north-south through volumes, delaying side-street motorists. This level of traffic indicates that Gardner Road south of the I-35 interchange might eventually need to be widened to four lanes to serve future development. At this particular intersection, signalization or turn prohibitions might eventually be necessary to improve side-street operations.

Overall, the 2030 No Action traffic operational analysis demonstrates that many key intersections in the study area are expected to reach or exceed capacity even with the planned transportation network improvements assumed in this analysis. These future operational deficiencies are predicted to occur regardless of the Proposed Action and any indirect effects of the Proposed Action.

In evaluating the No Action scenario, it became evident that several of the intersections would likely be improved by 2030 to address LOS issues associated with the projected traffic growth in the area. Therefore, an Improved No Action scenario was developed that included improvements that would be anticipated to occur in this time frame, but that have not been explicitly identified by state or local agencies. The effects of these potential improvements are summarized in the right half of Table 3-11. Each is discussed as follows:

- *Intersection #6 (US 56/Old US 56):* The improvements include signalization and widening of the Old US 56 approach to provide a second left-turn lane.
- *Intersection #21 (I-35 Southbound Ramps/Gardner Road):* The major improvement assumed at the interchange is widening the Gardner Road overpass to provide a 4-lane bridge (plus turn lanes). At Intersection 21, this would allow restriping to convert the outside southbound right-turn lane to a shared through/right-turn lane.
- *Intersection #22 (I-35 Northbound Ramps/Gardner Road):* With the widened Gardner Road bridge, the southbound approach would provide two through lanes and dual left-turn lanes (with the northbound on-ramp widened to accept them). The improvements also assume construction of a northbound right-turn lane.
- *Intersection #23 (Gardner Road/191st Street south):* The improvements include installation of a traffic signal.

<u>2030 Gardner No Action Freeway and Ramp Analysis</u>
The 2030 No Action freeway analysis assumed the forecasted volumes shown in Figure 3-10 and the projected 2030 mainline and ramp geometry (including mainline widening of I-35 to six lanes north of US 56). The resulting operational analysis (for both mainline and ramp junctions) is summarized in Table 3-12.

With the forecasted traffic increases described in the previous section, one freeway segment (I-35 northbound between US 56 and 151st Street) is projected to operate below the acceptable LOS threshold under 2030 No Action conditions:

- *I-35 mainline, US 56 to 151st Street:* This segment was projected to just exceed the LOS E threshold in the northbound direction during the a.m. peak hour without constructing the Proposed Action. This result suggests that additional capacity on this portion of I-35 may be required to accommodate long-term traffic volumes; however, no additional capacity has been planned in the LRTP.

Table 3-12: 2030 Gardner No Action Freeway Operational Analyses

3.2.4 2030 Gardner IMF Operations

2030 Gardner IMF Operations Forecasts

The 2030 trip generation approach for the intermodal facility was identical to that of the 2015 scenario, only with a higher annual lift count (870,000 in 2030 as compared to 495,000 in 2015) resulting in more trips – a total of nearly 6,045 vpd, including 563 during the a.m. peak hour and 388 during the p.m. peak hour. Table 3-13 summarizes the 2030 trip generation assumptions. The IMF trip distribution and assignment process employed the OTM and combined the results of surveys and other data to distribute truck traffic for the analysis. Additional information on the daily and peak hour trip generation and distribution is provided in Appendix A.

Table 3-13: 2030 Gardner IMF Operations Trip Generation

	Daily	AM Peak Hour in	AM Peak Hour out	AM Peak Hour total	PM Peak Hour in	PM Peak Hour out	PM Peak Hour total
Trucks	3,121	68	103	171	120	94	214
Bobtails	2,233	49	73	122	86	67	153
Non-Trucks	691	135	135	270	7	14	21
Total	6,045	252	311	563	213	175	388

Note: Bobtails are not typically measured at existing IMFs. A conservative estimate was calculated to capture potential bobtail traffic. Actual bobtail trips are likely to be less than what has been projected as trips will be generated by lifts and container staging.

The 2030 Gardner IMF Operations ADT and peak hour forecasts are illustrated in Figures 3-12 and 3-13 and the peak hour truck percentages are presented in Appendix C. The operational analysis for this scenario was conducted based on the 2030 Improved No Action geometry and the 2030 Gardner IMF Operations traffic volumes. The resulting LOS for all study locations are discussed in the following sections.

Figure 3-12: 2030 Gardner IMF Operations ADTs

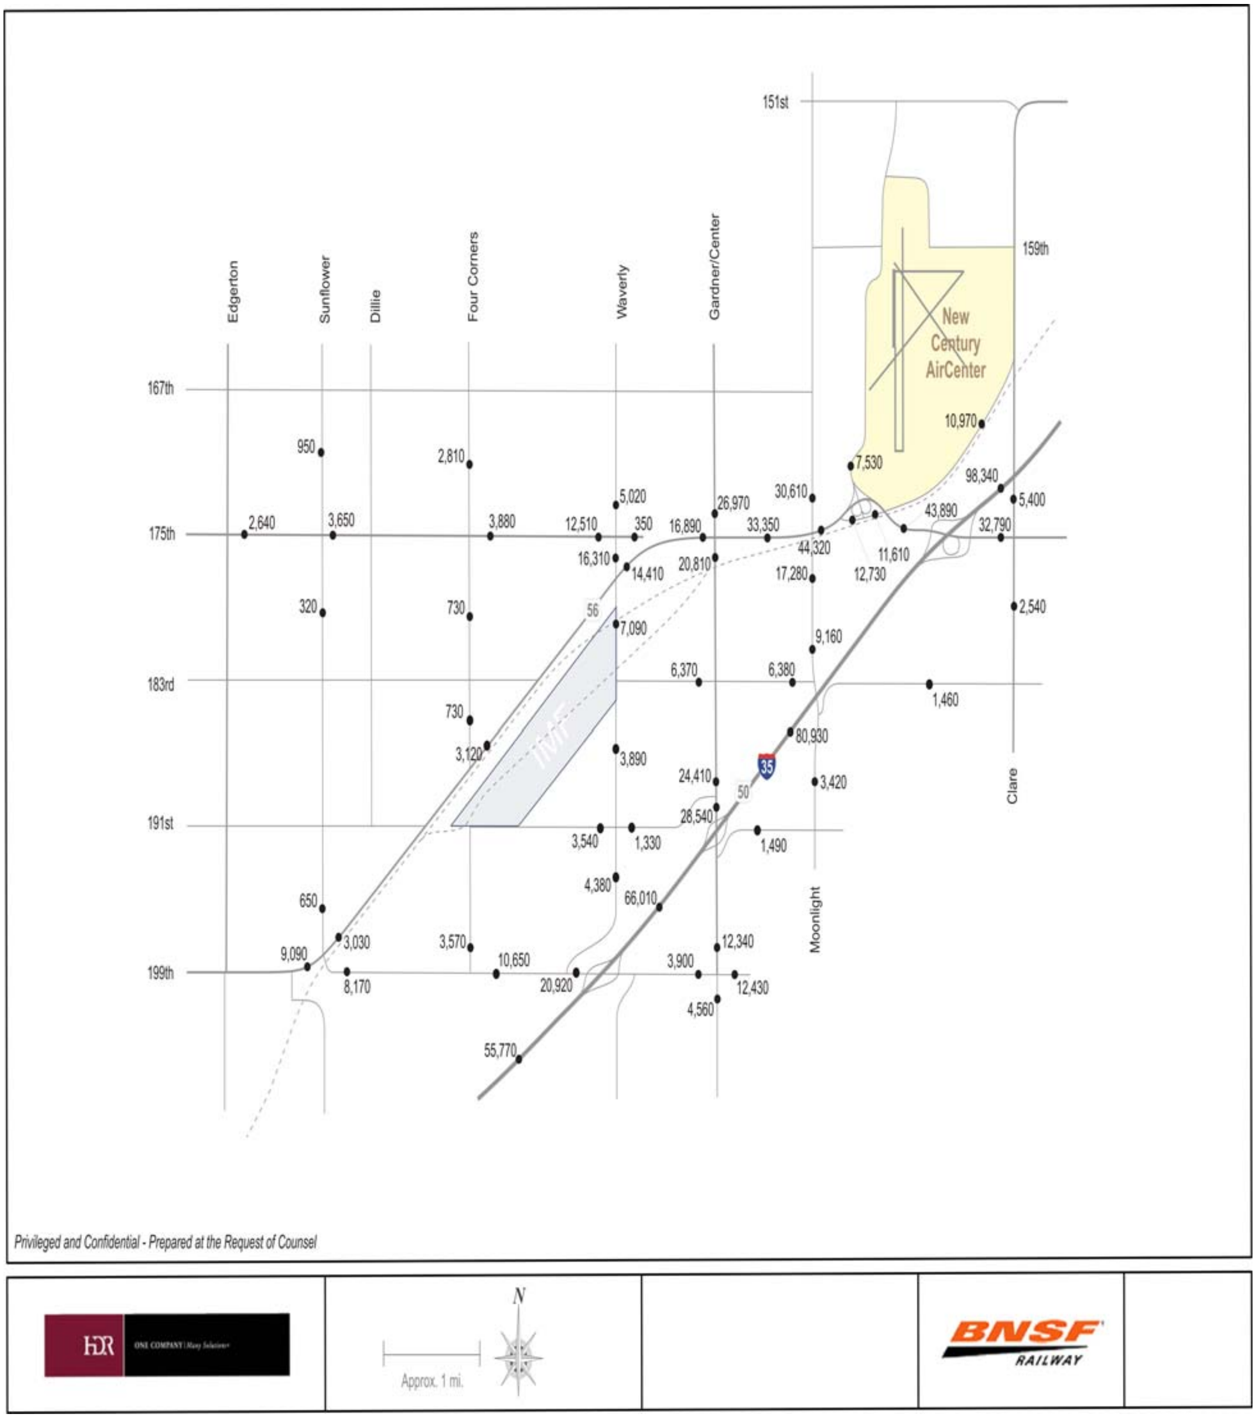

Figure 3-13: 2030 Gardner IMF Operations Turning Movement Volumes

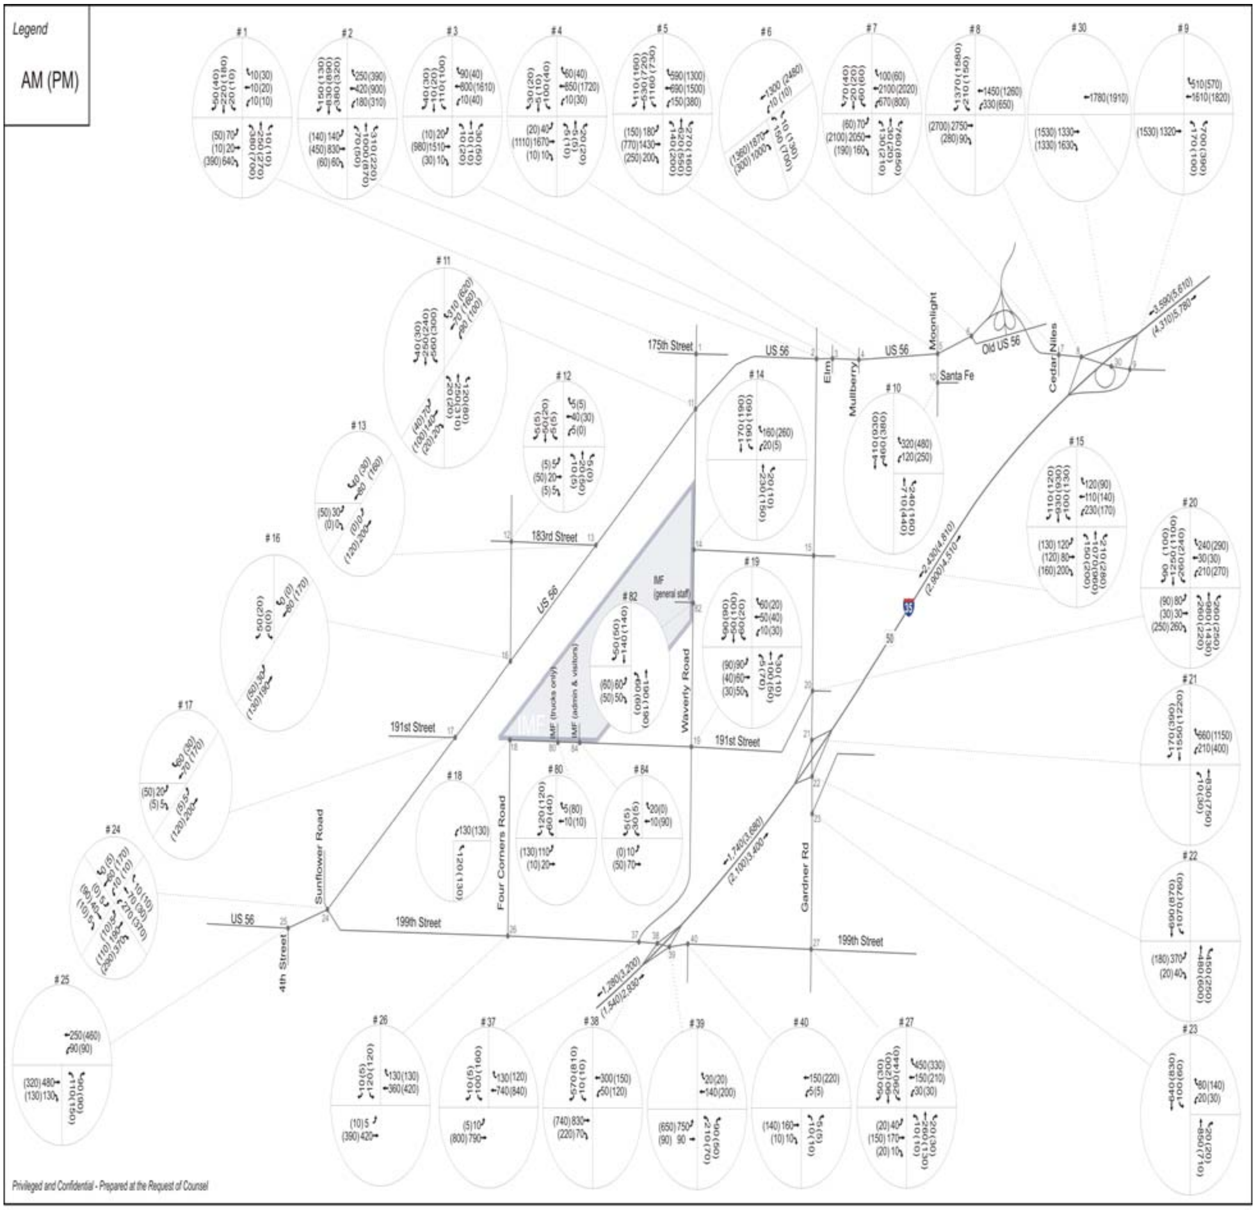

2030 Gardner IMF Operations Intersection Analysis

Table 3-14 summarizes the results of the intersection analysis for this scenario. As the table indicates, the three intersections that were projected to operate below the acceptable LOS threshold under the Improved No Action scenario are projected to continue to operate at the same LOS with the addition of the Proposed Action and associated indirect effects, with generally minor changes in delay. Because these intersections were predicted to experience LOS below the acceptable threshold without the Proposed Action, impacts to these intersections from the Proposed Action are considered to be minor. However, two additional intersections were predicted to operate below the acceptable threshold at LOS E or F:

- *Intersection #26 (199th Street/Four Corners Road)*: The southbound approach to the intersection is projected to operate at LOS E during the a.m. peak hour, and LOS F during the p.m. peak hour.
- *Intersection #37 (199th Street/Waverly Road):* The southbound approach to this future intersection is projected to operate at LOS E during the p.m. peak hour.

These LOS conditions are considered to be moderate impacts in 2030.

For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.

<u>2030 Gardner IMF Operations Freeway/Ramp Analysis</u>

Table 3-15 summarizes the results of the 2030 Gardner IMF Operations freeway analysis. As the table indicates, the one segment previously forecasted to operate at LOS E under 2030 No Action condition (I-35 from US 56 to 151st Street) is expected to continue to operate at LOS E in the 2030 Gardner IMF Operations scenario (with a 5 percent increase in density). This is considered a minor impact from the Proposed Action. In addition, the US 56 eastbound on-loop to I-35 is predicted to degrade from LOS D to LOS E during the a.m. peak hour. With the Proposed Action and associated indirect effects, the density in this merge area is forecasted to increase from 34.7 to 35.5, just crossing the LOS E threshold. Any capacity improvements that would address the northbound mainline LOS E identified in the 2030 No Action scenario would also improve this merge area to acceptable LOS resulting in a minor impact. As previously mentioned, no capacity improvements for this area are currently programmed in the LRTP. However, because this area would fail under the No Action scenario, these LOS issues are not considered to be significant impacts from the Gardner IMF.

In summary, although the analysis identified LOS degradation to LOS E for one ramp in comparison to the 2030 No Action scenario, the LOS would increase to acceptable levels with the improvements required to bring the No Action scenario to acceptable levels of service, and no other freeway or ramp mitigation measures are recommended.

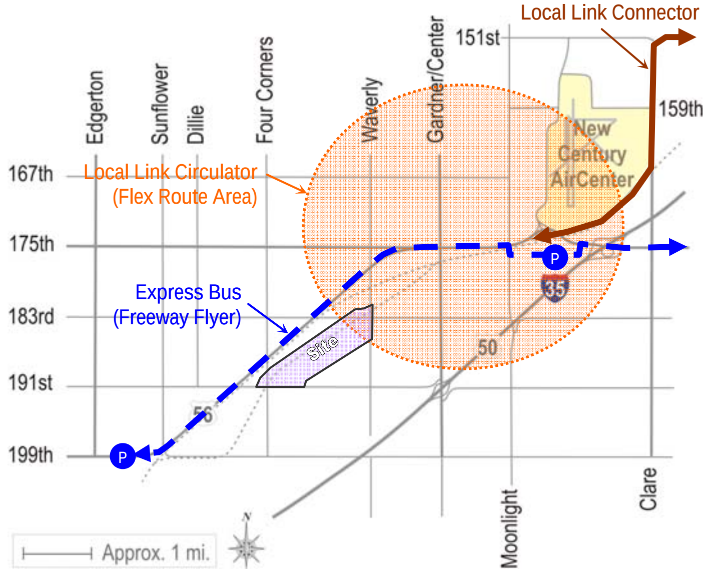
Notes: pc/mi/ln – passenger cars per mile per lane, LOS – Level of Service.

3.2.5 Transit

No Action

Figure 3-14: Long-Term Planned Transit Service



In the No Action scenario, no new transit service is expected to be provided to the development site vicinity in the short-term. However, the Regional Transit Plan (Smart Moves) includes long-term plans for extending the peak-period bus service south on US 56 to Edgerton and the addition of a new park-and-ride facility in Edgerton. These planned services are illustrated in Figure 3-14. The express bus service would come into the area on 175th Street (from US 169 and a transit center proposed for southern Olathe) and would continue on US 56 west to Edgerton (through Gardner). A local link circulator in the Gardner area is also proposed in the Smart Moves plan. The circulator would provide local service on weekdays (peak and midday) and weekends, but may not serve the Intermodal Facility area. Additionally, the plan shows a potential local link connector bus service running from the Gardner area to Olathe on Old US 56 and 151st Street.

Gardner Proposed Action and Future Gardner IMF Operations

Two types of transit service impacts are evaluated including: 1) increased demands on existing or planned service, and 2) demands for new service to serve the new development.

Regarding increased demands on existing or planned services, none of the employees are expected to use bus transit service on opening day as there is currently no transit service in the vicinity of the site. Furthermore, the two bus routes serving Gardner only provide peak period/peak direction service to Downtown Kansas City, Missouri. There is no service during off-peak periods, and even during the peak periods there is no service into Gardner in the morning or out of Gardner in the afternoon.

In the future, if the transit plans envisioned for the area are implemented, the peak period service would extend south on US 56 to Edgerton and a local circulator would be implemented in Gardner. The peak-period service would still not serve the intermodal site well, but the circulator could be designed with a stop at or near one or more of the site gates. However, the demand on either of these services related to the intermodal site is expected to be minimal for a number of reasons. One reason is that the off-peak, two-shift/three-shift nature of the work makes using transit for both trip ends difficult. For example, approximately 80 percent of the employees are expected to work a 12-hour two-shift schedule with employees either starting or ending a shift at 7:00 p.m., a time period that typically has low-frequency bus service in low-density areas. In addition, the lack of regional service coinciding with the shift-change peaks means that only local Gardner-area employees using the circulator route would really be able to access the site by bus.

In addition to the issues of shift-change schedules, bus routes/frequencies, and stop locations, there would be the larger issue of overall demand and the provision of bus service to a low-density employment site. The IMF site would have a low employment density with approximately 70 local employees on site during any one shift in 2010 (135 in 2030). This equates to an employment density of approximately one employee per 7.0 acres in 2010 and one employee per

3.5 acres in 2030. These employment densities are not typically consistent with the provision of regular scheduled bus service. In fact, service to these types of sites can have considerable cost, travel time, and delay implications for the service provider and other riders.

Therefore, no impacts are expected to the current or proposed transit service due to increased demand and no significant demand for new bus service is anticipated.

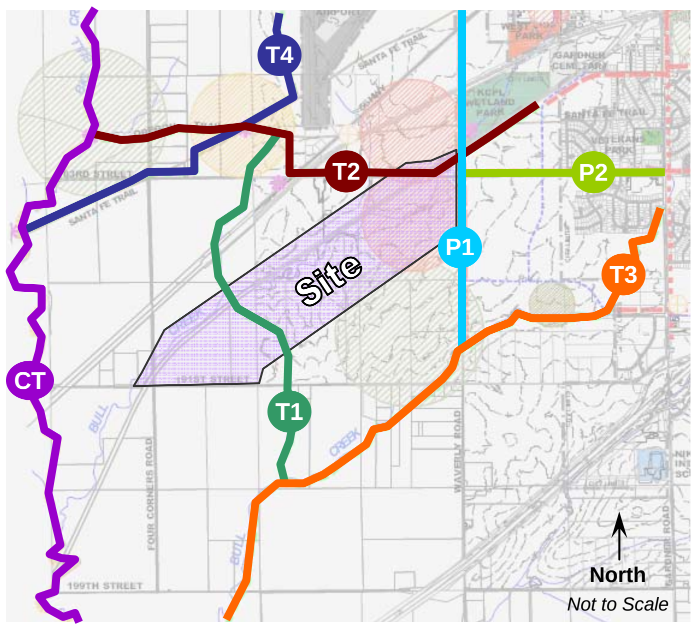
3.2.6 Pedestrian/Bicycle

<u>No Action</u>

Johnson County and City of Gardner documents were reviewed to determine if any new pedestrian and/or bicycle facilities are proposed for the area of the Intermodal site (Johnson County, 2004; Johnson County, 2001; City of Gardner, 2005a; City of Gardner, 2005b).

According to the *Johnson County Rural Comprehensive Plan Update* (2004) and the Johnson County Park and Recreation District *MAP 2020 - Master Action Plan* (2001) a potential trail is being considered along Big Bull Creek. It is shown and labeled as Trail CT in Figure 3-15. The trail would cross US 56 and the northern BNSF mainline track just west of the US 56 / 191st Street intersection. From there, the trail would follow the creek south into Big Bull Creek Park, crossing the existing southern BNSF mainline near 199th Street. According to *MAP 2020*, the Big Bull Creek Trail project would be implemented in the last four years of the 20-year park plan.

Figure 3-15:
Potential Future Trails



The City of Gardner Arterial Concept Pathway Plan map (dated June 2005) shows four potential future trails in the vicinity of the site. The first trail (T1) would run generally north-south in the vicinity of the Gardner site. It would cross US 56 and both the northern and southern BNSF mainlines approximately one-half mile east of Four Corners Road. It would then proceed south to cross 191st Street approximately two-thirds of a mile east of Four Corners Road. The second trail (T2) would run east-west along 183rd Street and the southern BNSF mainline between US 56 and Waverly Road. This trail would cross both BNSF mainline tracks. The third trail (T3) would run northeast-southwest near the Gardner site. It would cross Waverly Road just north of 191st Street and then cross 191st Street just west of Waverly Road. Trail T3 would continue south toward Big Bull Creek Park. The fourth trail (T4) would be located north of US 56 and would generally run northeast-southwest. It would follow a portion of the Old Santa Fe Trail between trails T2 and CT.

In addition to the above trails, two arterial pathways/bike routes are proposed: one along Waverly Road between US 56 and Trail T3 (P1), and one along 183rd Street (P2). These pathways are similar to paved trails or wide sidewalks, but they would be designed as joint-use facilities to serve both pedestrians and bicycles.

The City of Gardner plans to update its Trails and Pathways Plan as well as its Transportation Master Plan this year (2008). Based on communications with City staff, it is expected that major changes will be made to the proposed trails and pathways in the vicinity of the Proposed Action, and modified or additional pedestrian or bicycle facilities (such as bike lanes or routes) may be developed.

When the proposed new I-35 interchange is open to traffic, traffic on both Waverly Road and 199th Street is expected to increase. In order to provide for adequate pedestrian circulation and safety on these roadways, sidewalks, arterial pathways (such as the extension of the Waverly pathway), or paved shoulders (8-foot minimum) may be desirable in the longer-term No Action scenario.

<u>Proposed Action and Future Gardner IMF Operations</u>

The analysis presented in this section considered the potential pedestrian, bicycle, and trail activity or demand associated with the Proposed Action and the physical relationship of the Proposed Action to existing and proposed pedestrian, bicycle, and trail facilities.

In the near-term, pedestrian traffic to and from the IMF (i.e., off-site) is expected to be minimal. The primary reason for this is the long walk distances between the Proposed Action and most residential or retail destinations. The nearest subdivision entrance is nearly one mile from the main employee gate and even further from the actual on-site building locations. Second, as outlined previously, the number of on-site employees would be modest (under 70 on opening day and approximately 135 in 2030). A third reason is the off-peak two-shift/three-shift nature of the work. As mentioned in the transit section, approximately 80 percent of the on-site employees would work 12-hour shifts with shift changes at 7:00 a.m. and 7:00 p.m. This would mean that employees would have to walk after dark during a portion of the year.

Pedestrian activity may increase in the future if new development occurs within walking distance of the Proposed Action, but given the number of employees and the nature and dispersion of the on-site activity, it is not expected to be a major transportation mode for the site. The pedestrian activity that does result from the Proposed Action would principally be accommodated on the sidewalk proposed for 191st Street and the 8-foot shoulders proposed for Waverly Road. The provision of either sidewalks or full (8-foot) shoulders is important given the volume of Proposed Action truck traffic expected, especially on 191st Street. The planned arterial pathways (trails) on Waverly Road and 183rd Street could provide improved pedestrian access and safety when they are implemented. Based on contact with TAG-KC, the entity responsible for improving Waverly Road and 191st Street in the vicinity of the Proposed Action, the need for incorporating trail facilities along these roads is being coordinated with the City of Gardner and agreed upon provisions will be incorporated into the designs based on the updated trail plan (TAG-KC, 2008). This is consistent with the City street standards which state, "The design engineer shall contact the Parks and Recreation Department, Public Works, and/or Planning Department to determine whether any portion of the proposed construction will involve the City of Gardner's Trail System. Sidewalks constructed as part of this system shall be 10 feet in width with a 25-foot wide pedestrian easement."

Another consideration is the future construction of a new interchange on I-35. The main routes to this interchange (e.g., Waverly Road, and 199th Street) would benefit from either sidewalks or 8-foot minimum paved shoulders when that interchange is open to traffic. This could be addressed in the KDOT NEPA assessment of the new interchange and considered as part of that project's mitigation if warranted. It would also be beneficial if the City's proposed arterial pathway on Waverly Road were constructed (and extended further south) prior to the opening of the new interchange due to the increase in traffic on Waverly Road associated with the new interchange.

Bicycle activity is expected to be minimal for the same reasons that pedestrian activity is expected to be minimal. Special provision of bicycle routes or lanes is not typically necessary for this type of land use. In the near-term, any bicycle activity associated with the IMF would be adult work-based trips, and these trips could be accommodated on the planned paved roadways (or sidewalks on 191st Street). In the longer term, the new arterial pathways on Waverly Road and 183rd Street would also be available. When the new I-35 interchange is constructed, it may be beneficial to have bicycle provisions in place on roadways serving this interchange, including an extension of the City's planned arterial pathway on Waverly Road.

There are no existing facilities that would be physically impacted by the Proposed Action; however, the Proposed Action could affect some of the proposed facilities previously described. The City of Gardner has indicated that they expect to initiate a new Master Plan for trails and pathways later this year (City of Gardner, 2008a). City staff has indicated they expect major changes to the proposed trails and pathways in the vicinity of the Proposed Action to eliminate potential impacts. Therefore, the following potential impacts are expected to be resolved through the completion of the new Master Plan update:

- *Big Bull Creek Trail (CT)* – This trail would no longer have two separate railroad crossings. With the consolidation of the northern and southern BNSF mainline tracks into one right-of-way, a single larger structure could be used to cross all of the BNSF tracks (mainline and intermodal lead tracks).
- *Gardner Trail 1 (T1)* – The proposed north-south trail that would traverse through the project site would need to be rerouted, shortened, or eliminated because it would not be able to pass through the center of the intermodal site. There are other routing options, such as following US 56 south to the Big Bull Trail and then crossing US 56 and the railroad tracks in unison with that trail. This would allow the benefits of cost-sharing for construction of the crossing.
- *Gardner Trail 2 (T2)* – The proposed east-west trail along 183rd Street would also cut through the project site. It would need to be rerouted, shortened, or eliminated. One option would be to reroute the trail north along US 56, to connect with the pathway along Waverly Road. This would eliminate new railroad crossings and would make use of the proposed grade separation over the intermodal lead tracks on Waverly Road.
- *Pathway on Waverly Road (P1)* - The proposed pathway along Waverly Road could still be implemented as planned; however, use of the grade separation over the intermodal lead tracks on Waverly Road could be considered. As previously mentioned in the No Action section, special treatments for the path's at-grade crossing on Waverly Road may also be required (e.g., marked crossing, pedestrian scale signs, or guide fencing). Also, as mentioned previously, there is ongoing coordination between the roadway planners and the City regarding if and where trail facilities are needed along Waverly Road and 191st Street consistent with the update of the Master Plan.

3.2.7 At-Grade Rail-Highway Crossings and Delay

<u>No Action</u>

In the No Action alternative, the BNSF mainline train volumes would increase from 72 trains per average weekday in 2010 to 114 in 2030 as shown in Table 3-16. In addition, the train lengths are projected to increase over this time period. These changes would lead to increased blocked times and increased vehicular delay at all of the at-grade highway-rail crossing locations. As indicated in Table 3-17, the average blocked time per train would increase to just over three minutes per train by 2015. The average total blocked times are projected to be approximately 8:47 (min:sec) per hour in 2010, 9:56 per hour in 2015, and 15:14 per hour in 2030. These blocked time estimates are independent of the highway traffic volumes and are based on two at-grade crossings per roadway as outlined previously.

The number of delayed vehicles would increase over this 20-year period due to both increasing train and highway vehicle volumes. In the 2030 No Action scenario, approximately 25 to 40 percent of the highway vehicles at each crossing would be delayed to some extent, with the highest percentage at the Moonlight Road crossing.

Average vehicle crossing delays are projected to increase as well. The average vehicle delay for all vehicles would be approximately 13 to 16 sec/veh in 2010, increasing to 26 to 40 sec/veh in 2030 for the No Action Alternative. The average delay to delayed vehicles (i.e., average delay for vehicles present when a train is present) would not increase quite as much, from approximately 90 seconds in 2010 to 100 seconds per delayed vehicle in 2030. However, there would also be more delayed vehicles in 2030.

<u>Proposed Action and Future Gardner IMF Operations</u>
Changes to the at-grade crossings as a result of the Proposed Action include the following:

1. At-grade crossings on 183rd Street, Four Corners Road, and 191st Street would be eliminated due to road closures.
2. Use of the eastern at-grade crossing on 199th Street would be discontinued.
3. Grade separation over the east lead tracks would be constructed on Waverly Road.
4. Total train volumes would decrease at the Waverly Road at-grade crossing and Moonlight Road Crossings.
5. Highway traffic would increase, especially on Waverly Road and 199th Street.
6. Train speeds for intermodal trains entering or departing the Gardner IMF may be reduced (depending on the location and direction).
7. Grade separation over the westbound mainline and relocated eastbound mainline would be constructed on Waverly Road.

With regard to the decrease in total train volumes associated with the Proposed Action, the total number of trains south of the Gardner IMF would remain the same (Table 3-16). However, alongside and north of the IMF (i.e., at the Waverly Road and Moonlight Road crossings), the total number of trains would decrease because the intermodal trains to and from the West Coast (the amount of which exceeds those traveling to and from the east) would stop at the IMF and would not go further east. Because of this difference, the two sets of crossings are discussed separately.

Waverly Road and Moonlight Road Crossings
Based on the four changes previously outlined, the average blocked time per train would remain essentially the same at Moonlight Road and Waverly Road, while the total blocked time per hour would decrease by between 0:29 and 1:27 (min:sec) depending on the year and location (Table 3-17). Due to the reduction in total blocked time, the total number of delayed vehicles would decrease at Moonlight Road. At Waverly Road, the number of delayed vehicles would increase due to increases in highway vehicles at that location. The average delay per vehicle decreases slightly at both locations except in 2030 where it increases by two to three seconds at Waverly Road. The average delay per delayed vehicle at both locations would be about the same as in the No Action scenario.

Other Crossing Locations
For the locations south of the intermodal facility, the blocked time would increase with the Proposed Action as shown in Table 3-17. The blocked time per hour would increase the most on 199th Street, with an increase of 26 seconds to 9:13 per hour in 2010 and an increase of approximately one minute to 16:16 per hour in 2030. The average blocked time per train at 199th Street would be 3:26 in 2030 (13 seconds higher than the No Action condition). The number of delayed vehicles would increase the most on 199th Street (by approximately 50 vehicles during each peak hour in 2030). On 199th Street, delay per vehicle would increase by 6 to 7 sec/veh in 2030, while the delay per delayed vehicle would increase by 9 sec/veh in 2030. The changes to

blocked time and delay on Nelson Street would be somewhat less. Changes to 207th Street and Edgerton Road would be modest to minor and affect very few additional vehicles.

Based on Table 3-17, 199th Street is expected to experience the largest increases in blocked time and crossing delay in comparison to the No Action scenario. The average blocked time increase would be 7 percent in 2030. The average delay increase (for all vehicles) would be 20 percent in 2030; however, the average delay would remain below 40 sec/veh.

The effects of the Proposed Action and Future Gardner IMF Operations in comparison to the No Action scenario are summarized as follows:

- *Moonlight Road* – decrease in total blocked time and delay;
- *Waverly Road* – decrease in total blocked time, delay decrease in 2010 and 2015, delay increase in 2030 due to higher highway volumes;
- *183rd Street*, *Four Corners, 191st Street* – crossings closed;
- *199th Street* – increased blocked time (increase of 1:02 per hour in 2030), increase in delayed vehicles (54 in 2030 p.m. peak), increase in average delay per vehicle (7 sec/veh in 2030 p.m. peak);
- *Nelson Road* – increased blocked time (increase of 0:52 per hour in 2030), increase in delayed vehicles (11 in 2030 p.m. peak), increase in average delay per vehicle (4 sec/veh in 2030 p.m. peak);
- *207th Street* - increased blocked time (increase of 0:26 per hour in 2030), increase in delayed vehicles (3 in 2030 p.m. peak), increase in average delay per vehicle (2 sec/veh in 2030 p.m. peak);
- *Edgerton Road* – minor change.

Overall, the majority of the anticipated blocked time and delay in the Proposed Action scenario would be due to through trains, which are not affected by the Proposed Action. In addition, the forecasted overall average delay per vehicle would never exceed 40 seconds. The average delay to delayed vehicles would increase from around 100 seconds in the No Action scenario to a maximum average value of 109 seconds in 2030 at 199th Street in the Proposed Action scenario. Therefore, delay impacts as a result of the Proposed Action are not considered significant.

3.2.8 Emergency Vehicle Access

No Action

In the No Action scenario, emergency vehicle access routing and distances are expected to remain as outlined in Section 2.1.8 (Figure 2-7). There are, however, two future changes that would affect emergency vehicle access: the volume of train traffic is expected to increase over time and the average length of those trains is expected to increase. These changes would increase the potential for delay (and longer delays) when responding vehicles must cross railroad tracks. The increase in at-grade crossing delay in the No Action scenario is outlined in Section 3.2.7.

Proposed Action and Future Gardner IMF Operations

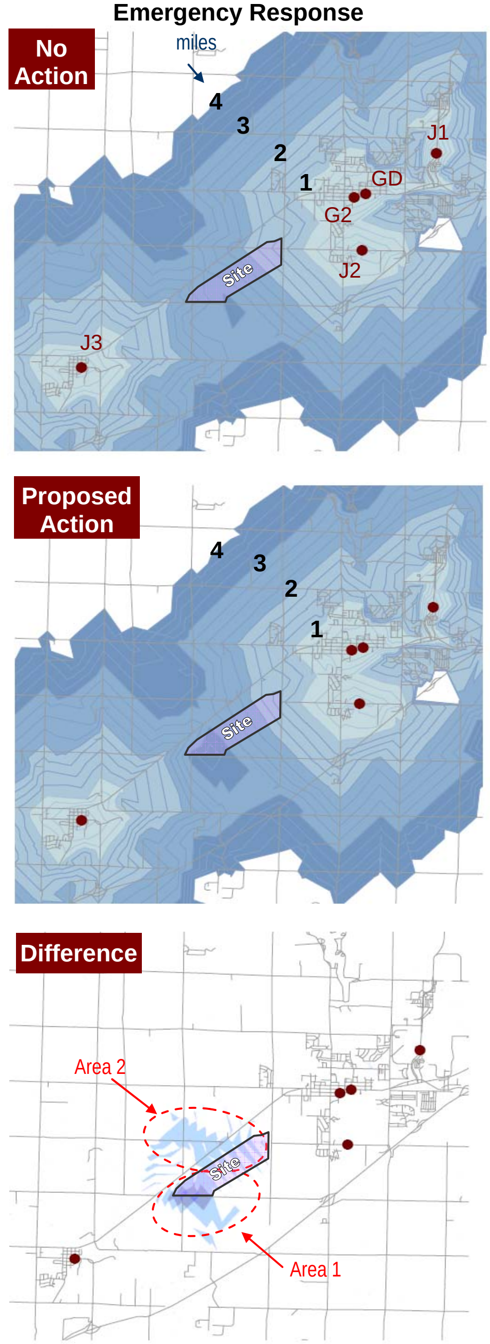
The construction of the Proposed Action would result in changes to the local roadway network as well as to the current railroad track alignment. The modifications that pertain to emergency vehicle access are highlighted here:

- 183rd Street would be closed from US 56 to Waverly Road.
- 191st Street would be closed from US 56 to Four Corners Road.
- Four Corners Road would be closed from US 56 to 191st Street.

- The eastern railroad crossing on 199th Street would be eliminated, and the west crossing would be widened to accommodate additional tracks.
- The northern crossing of Waverly Road would be double tracked and grade separated.
- The southern crossing of Waverly Road (new lead tracks) would be grade separated.
- Train volumes at all but two rail-highway at-grade crossings would remain unchanged, but average train speeds at key locations would change (*At-Grade Rail-Highway Crossings and Delay*, Section 3.2.7).

The aforementioned closures and adjustments would not change the majority of Emergency Vehicle Response EVR distances outlined in the Section 2.1.8. In fact, only two areas would be affected. Figure 3.16 shows the EVR distances with the closures anticipated as part of the Proposed Action. (As on Figure 2-7, the stations shown on Figure 3-16 are: [J1] - Johnson Co. FD No. 1 Station #1, [J2] - Johnson Co. FD1 Station #2, [J3] - Johnson Co. FD1 Station #3, [G2] - Gardner Plum Creek Station #2, and [GD] - Gardner Department of Public Safety). The outer four-mile bands would remain constant and the Proposed Action Site would also remain within four miles of one or more stations. A comparison of the No Action and Proposed Action figures is provided at the bottom of Figure 3-16 and the two areas with changed response distances are described.

Figure 3-16: Change in Distance from Emergency Response



As illustrated, there would be a small area in the vicinity of 191st Street and Four Corners Road (Area 1) where emergency vehicle response distances would increase by 0.25 to 0.5 mile. This change is due to the 191st Street closure, which would make 199th Street the new shortest distance for EVR from the Edgerton Station to this area. Emergency response vehicles from the Gardner area would have a somewhat longer response distance, but they can reach this area without crossing any active rail lines at-grade. In fact, with the relocation of the southern BNSF mainline, stations in Gardner can serve any site east of the tracks without crossing a rail line at-grade. Thus while in some cases the response distances might be longer than from the Edgerton station, the response times would be more certain from Gardner. The potential at-grade highway-rail grade crossing delay associated with the Proposed Action is addressed in Section 3.2.7, *At-Grade Rail-Highway Crossings and Delay*.

There is also an area in the vicinity of 183rd Street, US 56, and Four Corners Road for which the response distances would increase by 0.25 mile (Area 2). This is due to the 183rd Street closure, which would mean that the Gardner Plum Creek Station #2 would no longer be the nearest station. Instead, Johnson County FD No. 1 Station #2 and Johnson County FD No. 1 Station #3 would become the nearest stations. Stations in both downtown Edgerton and Gardner could both respond to this area without crossing any active rail lines at-grade.

A third area of interest, not highlighted because it is not affected by any road closures, is service within Edgerton, specifically, access from Johnson County Fire Station #2 [J3] to areas east of the railroad tracks in the vicinity of Sunflower Road. A review of the expected average train speeds along this corridor shows that outbound intermodal trains (leaving the IMF) would travel slower than typical through trains (on average) at both Nelson Street and 207th Street. Inbound intermodal trains would travel faster on average than through trains at 207th Street, but slower at Nelson Street. Therefore, in 2015, between six and seven times per day there would be trains entering or leaving the IMF that would pass Nelson Street traveling slower than through trains. At 207th Street this would only occur three times per day. The Edgerton Road crossing is far enough south of the IMF that the average inbound IMF-train speed would slightly exceed the average through-train speed; and the outbound IMF-train speed would be slightly slower(within 2 mph) than the average through-train speed.

3.2.9 Circulation System

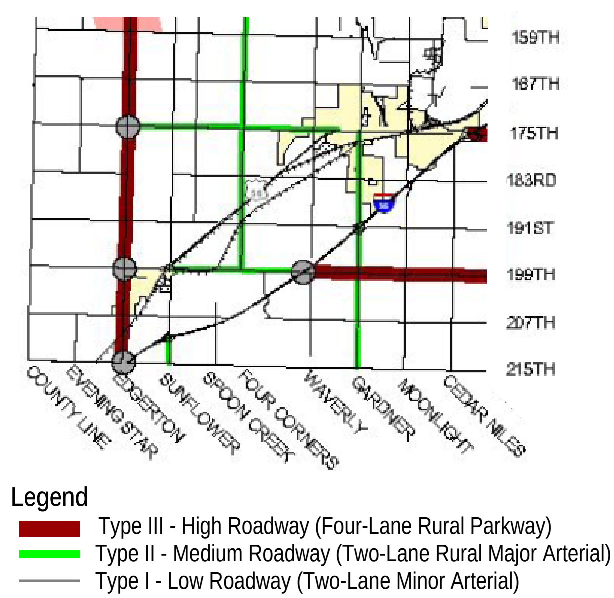
<u>No Action</u>

In the No Action Scenario, the local and regional connectivity would remain similar to what it is today, with the following exceptions:

1. Development would continue in the area. This would likely include more dense development in the areas with water and sewer service.
2. Railroad traffic on the southern transcontinental mainline would continue to increase (as outlined previously), leading to increased potential for delay at mainline railroad crossings.
3. Before 2030 (and as soon as late 2015), a new interchange is planned for I-35 in the vicinity of Waverly Road, 199th Street, or Homestead Lane. The exact location is currently under study by KDOT, but for purposes of this analysis it was assumed to be near 199th Street and Waverly Road as shown on the current County plan.

The Johnson County Comprehensive Arterial Road Network Plan (CARNP) shows future improvements to selected roadways in the vicinity of the Proposed Action (Figure 3-17). The CARNP is the County's principal transportation planning document and was adopted by the County Commissioners in 1999. In addition, the more recent Johnson County Rural Comprehensive Plan (June 2004) adopted the 1999 CARNP as the transportation plan for Southwestern Johnson County. The CARNP shows a new grade-separated access point on I-35 at 199th Street near Waverly Road. It also shows upgrades to 199th Street to provide improved east-west connectivity in the vicinity of the interchange. Specifically, 199th Street is shown as a four-lane rural parkway (Type III - High Roadway) east of I-35. West of I-35, 199th Street is proposed as a two-lane rural major arterial (Type II - Medium Roadway). Four Corners Road, Gardner Road/Center Street, and 175th Street are

Figure 3-17:
Johnson County CARNP – Gardner Area



all shown as two-lane rural major arterials (Type II – Medium Roadway). Waverly Road, 191st Street, and 183rd Street are shown as two-lane minor arterials (Type I – Low Roadway).

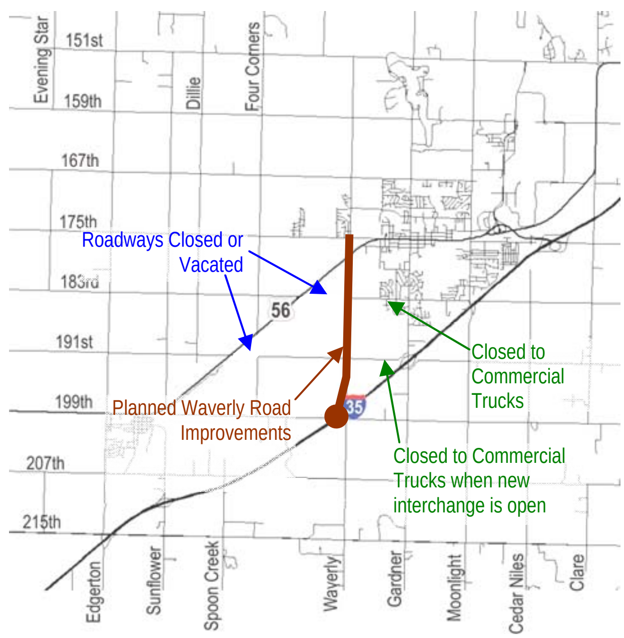
Based on the CARNP, local connectivity in the vicinity of the Proposed Action would be improved by upgrading existing collector roadways to arterials (199th Street, Four Corners Road, Gardner Road, and 175th Street). Two of these roadways are north-south and two are east-west. They all already cross existing barriers. They also strengthen the grid network form (they form a rectangle) south and west of Gardner. Regional connectivity is improved through the addition of a second interchange on 199th Street near Waverly Road. Thus travelers would have two options for interstate highway access: Gardner Road and 199th Street near Waverly Road.

Plans by the City of Gardner and Johnson County to re-align 191st Street to connect with the existing 188th Street roadway section will also modify circulation in the area. It will improve traffic operations on Gardner Road in this area as it will provide significantly more distance between the southbound I-35 interchange ramp intersection and the first major intersection to the north.

<u>Proposed Action and Future Gardner IMF Operations</u>

With the Proposed Action, circulation in the vicinity of the Gardner IMF would be changed in part due to the closure of sections of 191st Street, Four Corners Road, and 183rd Street as shown in Figure 3-18. Closure of these roadways would necessitate that drivers use alternative routes through the area. In addition, 183rd Street (just west of Gardner Road) would be closed to through commercial truck traffic. 191st Street (between Waverly Road and Gardner Road) would also be closed to through commercial truck once the new I-35 interchange is constructed. Therefore, the circulation system for commercial trucks would be somewhat more limited than for autos.

Figure 3-18: Roadway Network Changes



Until the new interchange is constructed, it is recommended that the re-aligned 191st Street/188th Street and Gardner Road be promoted as the main route to and from I-35 for all IMF truck traffic. This could include on and off-site signage directing truck drivers to use this route (and to discourage the use of prohibited routes). It could also include other means by which directions are communicated to truck drivers traveling to and from the IMF. This recommendation would carry forward into the future Gardner IMF Scenarios, with adjustments made as necessary when the new I-35 interchange is constructed. The City of Gardner is considering changes to their current designated truck routes.

As noted, the Proposed Action would eliminate three pieces of the current grid system south and west of Gardner. Currently, Four Corners Road is a collector roadway and the other two are local (gravel) roadways. They all currently carry low traffic volumes (approximately 100 to 250 ADT). The CARNP classifies Four Corners Road in the future as a two-lane rural major arterial (Type II – Medium), while the other two are classified as two-lane rural minor arterials (Type I – Low). The approximate 2030 traffic volumes in the No Action scenario for the road sections proposed for closure are: Four Corners Road – 3,720 ADT, 191st Street - 270 ADT, and 183rd Street – 1,010 ADT. Based on these volumes, it appears that these segments of 191st Street and 183rd

Street would not be critical to the overall highway system in 2030. Four Corners Road, however, would carry a larger amount of traffic.

With the closure of the aforementioned roadways, traffic volumes on 199th Street and Waverly Road are expected to increase in comparison to the No Action scenario. The increase on 199th Street is forecasted to be approximately 530 vpd (6.9 percent) just east of US 56. This would include some traffic from the Gardner IMF. The increase on Waverly Road is expected to be more appreciable as it would become the major alternative to Four Corners Road (This is demonstrated in part by the increase of only 230 vpd on Sunflower Road just north of US 56). Traffic on Waverly Road, a low volume roadway, is forecasted to increase from 2,180 to 7,090 (4,910 vpd, or 225 percent) just south of US 56. Waverly Road would still be able to accommodate the traffic volumes shown in the Proposed Action scenario as a two-lane highway. Some of this increase would be traffic generated by the Proposed Action, but much of it would be local traffic re-routed by the road closures including traffic headed to and from the new interchange on I-35 near Waverly Road. Therefore, with the combination of the Proposed Action and the new interchange, Waverly Road would become a primary arterial highway in the local grid system. These potential shifts in traffic flow and circulation, while considerable, are not anticipated to have a significant negative effect on traffic circulation and connectivity of the area. Regarding, east-west flows, it appears that the traffic from 191st Street and 183rd Street would disperse to various roadways (199th Street, US 56, Waverly Road to 183rd Street), and the Proposed Action street network appears sufficient to accommodate these shifts with minor impacts.

3.2.10 Roadway Design Considerations

<u>No Action</u>

In the No Action Scenario the highway system could be expected to continue to evolve in a manner consistent with past trends. This would include periodic roadway upgrades as needed to meet future state and local roadway design standards. In the immediate vicinity of the IMF, the major improvements expected to be made in the 2010 and 2015 time frames include the KDOT improvements related to Gardner Road. In the 2030 No Action Scenario it is assumed that a number of local roadways would be improved per the CARNP recommendations. This is in keeping with the anticipated development in the area not related to the Proposed Action and the assumption of a new interchange on I-35 serving the 199th Street and Waverly Road corridors. The local roadway improvement could include paving 183rd street, Waverly Road, and 191st Street to bring them up to rural two-lane Type I standards (The example of a rural two-lane Type I roadway given in the CARNP is West 143rd Street, which is a two-lane roadway with minimal shoulders and few if any turn lanes). Based on the CARNP, Four Corners Road and 199th Street would be improved to rural two-lane Type II standards (The example of a two-lane Type II roadway given in the CARNP is 175th Street from I-35 to US 169, which has paved shoulders and turn lanes as needed at major intersections).

<u>Proposed Action and Future Gardner IMF Operations</u>

With the construction of the Gardner IMF, a number of the roads previously anticipated to be upgraded in the longer term would be upgraded in the near term. This would include upgrades to both 191st Street and Waverly Road. These roads would be designed to meet applicable state and local standards, including pavement depth and type appropriate for the projected auto and truck traffic. Separate from the Proposed Action, Gardner Road, which is a local collector roadway, is being improved by KDOT to be four lanes with signals from 188th Street/191st Street south to the I-35 interchange. In the 2010 and 2015 Scenarios, the vast majority of IMF truck traffic is anticipated to use the re-aligned 188th Street/191st Street and Gardner Road to travel to and from I-35. For example, in 2015, 191 out of 209 p.m. peak-hour IMF trucks are forecasted to use this route (over 91 percent). This would minimize any potential near-term effects on other local roadways such as Four Corners Road and 199th Street.

By 2030, a new I-35 interchange between the Cities of Gardner and Edgerton is forecasted to attract the vast majority of IMF truck traffic. IMF trucks would use a combination of the new Waverly Road connection between 191st Street and 199th Street and the Four Corners Connection to 199th Street to reach this interchange, however, a new Waverly Road connection would presumably be built to the appropriate design standards, taking the expected truck usage into account. The CARNP plan calls for improving 199th Street to support forecasted area/corridor development and to facilitate connections to I-35 as mentioned in the No Action Scenario. Therefore, Four Corners Road could experience truck volumes for which it is not designed. However, given the closure of Four Corners north of 191st Street, non-IMF traffic on that roadway is likely to be minimal.

The City's planned re-alignment of 191st Street to connect with 188th Street would also improve safety along Gardner Road in this area as it will provide significantly more distance between the southbound I-35 interchange ramp intersection and the new main access point to the realigned 188th Street/191st Street.

For 2010, 2015, and 2030, there are no anticipated major conflicts between school traffic and IMF truck traffic currently anticipated. For example, in 2015 no IMF trucks are projected to use Gardner Road south of I-35 (in the vicinity of the Nike Elementary School) during the 7:00 to 8:00 a.m. hour. On Waverly Road north of US 56, in 2015 two trucks are projected during this a.m. peak hour. No IMF trucks are projected to use US 56 just west of Waverly and seven trucks are projected on US 56 east of Waverly road during the a.m. peak hour.

3.2.11 Construction Traffic

Construction of the Proposed Action including related infrastructure is currently anticipated to occur over a period of 18 to 22 months. Major road and bridge construction would potentially be completed in the first 12 months. Construction staging areas would mainly be on-site, though some off-site areas may be used related to roadway and bridge construction.

Construction of the roads and bridges could necessitate short-term full and partial road closures; however, access to all homes and properties along the affected roadways would be maintained during construction, thereby limiting impacts to local residents and property owners.

The primary expected types of construction include construction employee traffic, equipment/supply traffic, and material hauling traffic. However, it is not currently known how much construction traffic in each category would be generated by the Proposed Action. There would be many different contractors involved in the project and the extent, approach, and schedule of work for each type of contractor is not known. However, as part of the development of construction phasing and implementation plans, a traffic management plan would be developed in conjunction with the City of Gardner, the City of Edgerton, and Johnson County.

The traffic management plan would also address the routes to be used for construction traffic entering and exiting the site. There are a number of possible major routes for construction traffic traveling to and from the site. As part of the plan development, the various routes would be considered and the preferred routes for each phase of the project would be developed. These phased plans will address topics such as temporary and permanent road closures as well as the construction of the upgraded roadways of 191st Street and Waverly Road. For example, once 191st Street is complete and open to traffic it may become a major route for construction traffic to the site. The construction planning could account for the origins and destinations of materials and equipment on the site as well as the maintenance of adequate emergency access to all parts of the site during construction.

3.3 Indirect Effects - Future Gardner IMF Operations plus Induced Development

This section presents the indirect effects analysis of the proposed Gardner IMF. The reasonably foreseeable indirect effects considered are 2.86 million square feet of warehouse development by TAG-KC of a logistics park, known as the Logistics Park Kansas City. The Logistics Park Kansas City (Crandall VS, 2008) will consist of freight distribution and warehouse facilities. Trip generation and distribution assumptions for the Logistics Park-generated trucks were based on published research, regional commodity flow data, and the aforementioned agency consensus process. The trip generation and distribution assumptions for the Logistics Park are documented in more detail in Appendix A. Detailed operational analysis results are included in Appendix F.

3.3.1 2010 Gardner IMF Operations plus Induced Development

<u>2010 Gardner IMF Operations plus Induced Development Forecast Volumes</u>

The traffic generated by the Proposed Action is discussed in Section 3.1.2. With an opening-day annual lift count of approximately 375,000 to 415,000 (Brian Decker Verified Statement [Decker VS], 2008), it is estimated that the Gardner IMF would generate approximately 2,900 vpd in 2010, including 273 during the a.m. peak hour and 185 during the p.m. peak hour (Table 3-18). As previously described, the table separately identifies bobtails (unloaded trucks with no chassis). Additionally, the table includes trip generation from the Logistics Park Kansas City, which is expected to occupy between 400,000 and 600,000 square feet on opening day and generate approximately 2,300 vpd, including 111 during the a.m. peak hour and 185 during the p.m. peak hour. More detailed information on trip generation is provided in Appendix A.

Table 3-18: 2010 Gardner IMF Operations Plus Induced Development Trip Generation

		AM Peak Hour			PM Peak Hour		
	Daily	in	out	total	in	out	total
IMF							
Trucks	1,489	32	49	81	57	45	102

Non-Trucks	2,185	156	75	231	64	80	144
Total	5,212	217	167	384	171	164	335

The 2010 Gardner IMF Operations plus Induced Development ADT and peak-hour forecasts are presented in Figures 3-19 and 3-20 and the peak hour truck percentages are illustrated in Appendix C.

<u>2010 Gardner IMF Operations plus Induced Development Geometry Assumptions</u>

The base geometric assumptions for this scenario are identical to those assumed for the 2010 Gardner Improved No Action scenario.

Figure 3-19: 2010 Gardner IMF Operations plus Induced Development ADTs

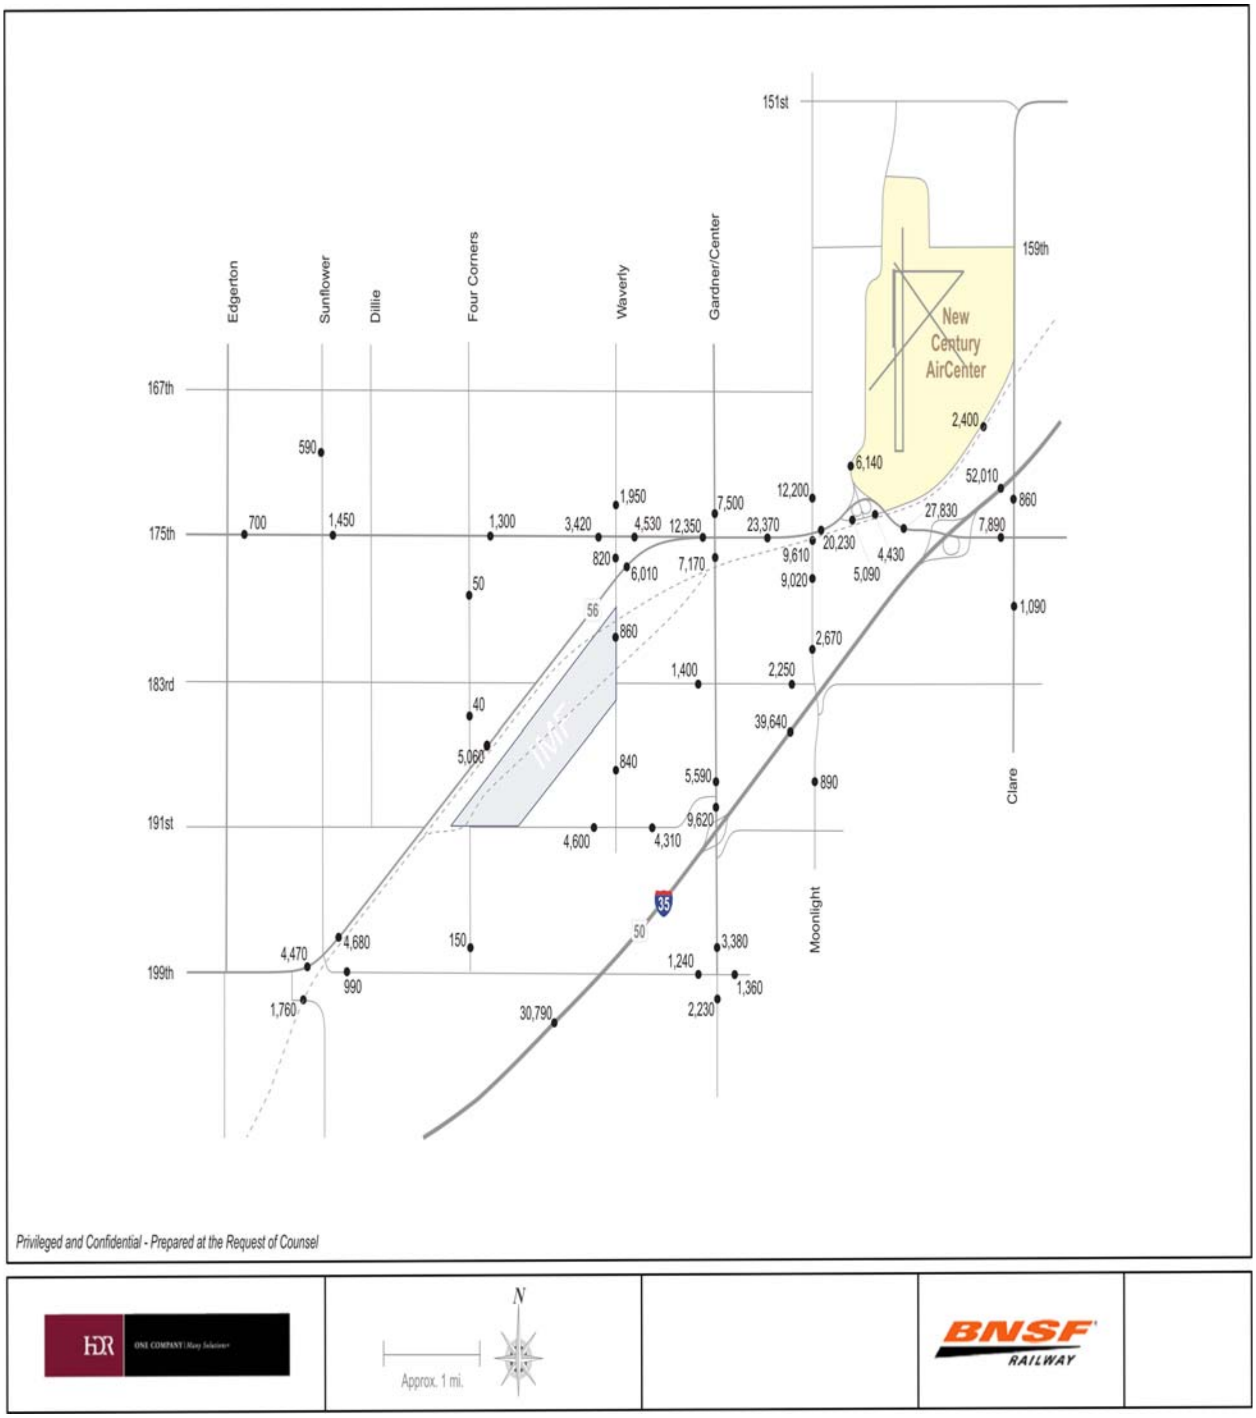

Figure 3-20: 2010 Gardner IMF Operations plus Induced Development Turning Movement Volumes

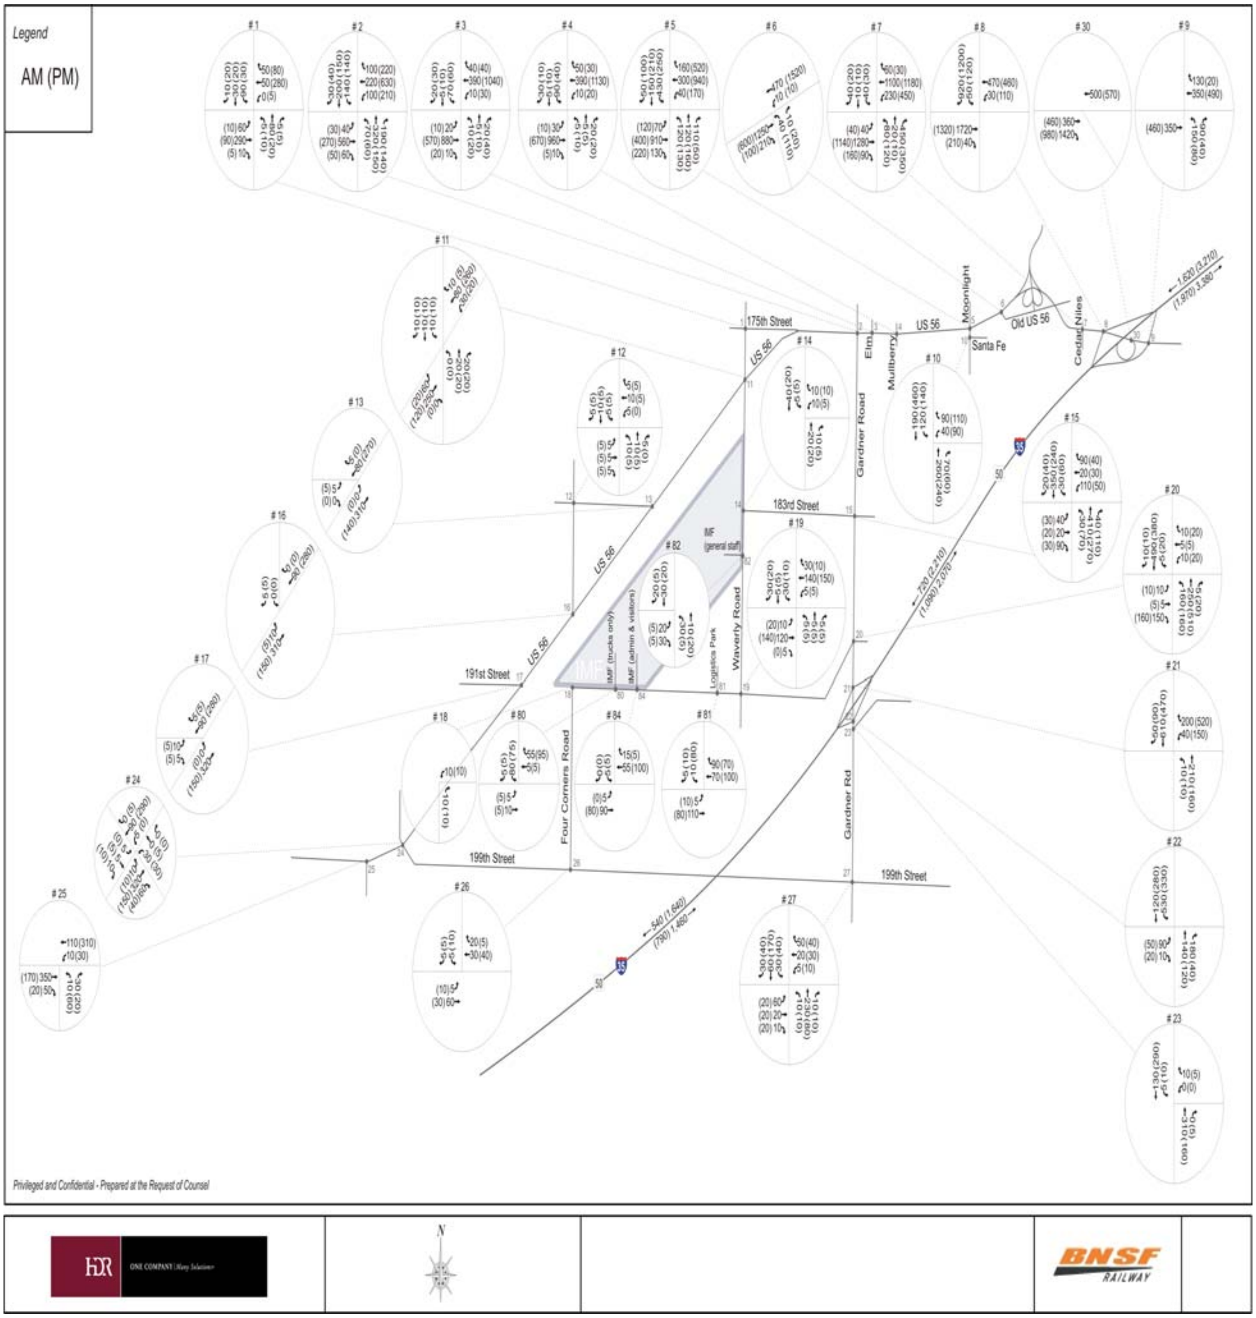

<u>2010 Gardner IMF Operations plus Induced Development Intersection Analysis</u>

Table 3-19 summarizes the results of this scenario, and provides a comparison to the 2010 No Action and 2010 Proposed Action scenarios. As the table indicates, all study intersections are projected to continue to operate at LOS D or better under this scenario. Therefore, there would be only minor impacts to intersections as a result of the Proposed Action plus induced development in the first year of operations.

Notes: pc/mi/ln – passenger cars per mile per lane, LOS – Level of Service.

3.3.2 2015 Gardner IMF Operations plus Induced Development

<u>2015 Gardner IMF Operations plus Induced Development Forecast Volumes</u>

Under this scenario, the Gardner IMF is projected to operate with 495,000 annual lifts and generate nearly 3,500 vpd, including 335 during the a.m. peak hour and 222 during the p.m. peak hour. The Logistics Park Kansas City is expected to occupy 2.86 million square feet and generate approximately 11,000 vpd, including 530 during the a.m. peak hour and 716 during the p.m. peak hour (Table 3-21).

These trips were assigned to the traffic study area roadways using procedures described earlier in this document and detailed in Appendix A.

The 2015 Gardner IMF Operations plus Induced Development scenario ADT and peak-hour forecasts are presented in Figures 3-21 and 3-22. Peak hour truck percentages are illustrated in Appendix C.

Table 3-21: 2015 Gardner IMF Operations plus Induced Development Trip Generation

	Daily	AM Peak Hour in	AM Peak Hour out	AM Peak Hour total	PM Peak Hour in	PM Peak Hour out	PM Peak Hour total
IMF							
Trucks	1,776	39	58	97	68	54	122
Bobtails	1,270	28	42	70	49	38	87
Non-Trucks	430	84	84	168	5	8	13
Total	3,476	151	184	335	122	100	222
Logistics Park							
Trucks	2,254	31	38	69	42	34	76
Non-Trucks	8,781	423	38	461	287	353	640
Total	11,035	454	76	530	329	387	716
IMF+ Logistics Park							
Trucks	4,030	70	96	166	110	88	198
Bobtails	1,270	28	42	70	49	38	87
Non-Trucks	9,211	507	122	629	292	361	653
Total	14,511	605	260	865	451	487	938

Note: Bobtails are not typically measured at existing IMFs.
A conservative estimate was calculated to capture potential bobtail traffic. Actual bobtail trips are likely to be less than what has been projected as trips will be generated by lifts and container staging.

<u>2015 Gardner IMF Operations plus Induced Development Geometry Assumptions</u>

The base geometry assumptions for this scenario are identical to those of the 2015 Gardner No Action scenario.

Figure 3-21: 2015 Gardner IMF Operations plus Induced Development ADTs

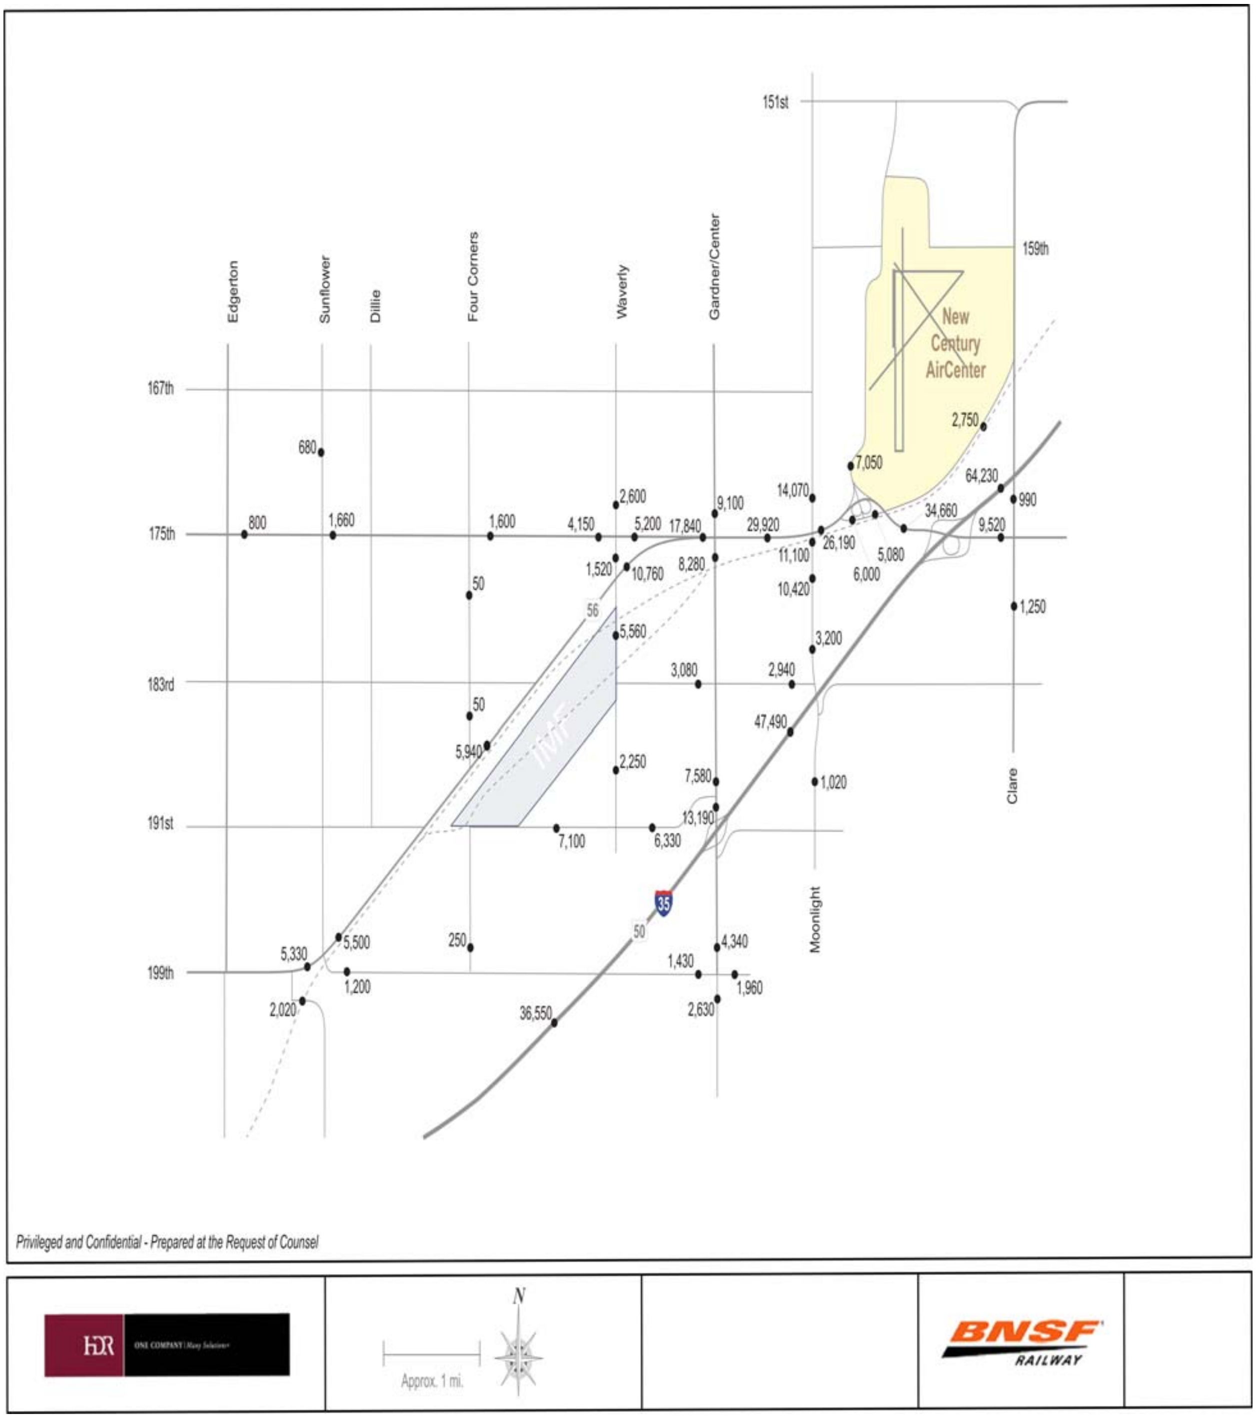

Figure 3-22: 2015 Gardner IMF Operations plus Induced Development Turning Movement Volumes

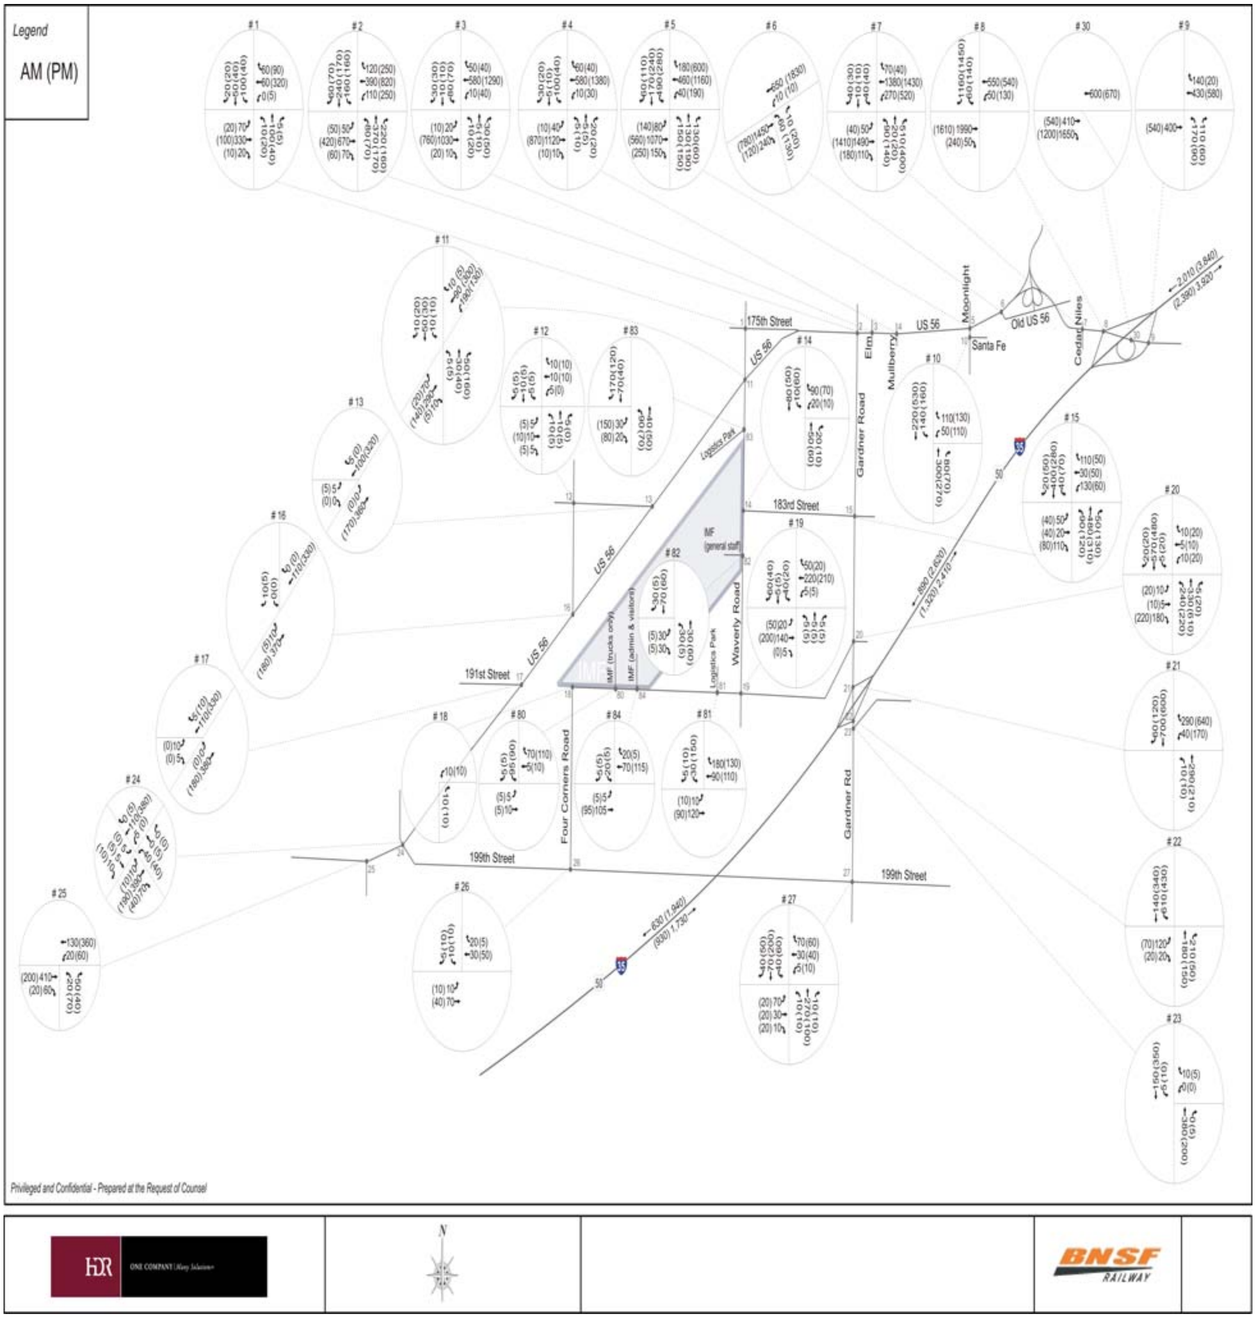

2015 Gardner IMF Operations plus Induced Development Intersection Analysis

The results of the intersection analysis for this scenario are shown in Table 3-22. The 2015 analysis forecasted that two study intersections would operate at LOS E or worse during the a.m. peak hour as a result of induced development. The intersections evaluated, and their forecasted operations under the No Action and 2015 Gardner IMF operations plus induced development scenarios are described below and highlighted in Table 3-22:

- *Intersection #11 (US 56/Waverly Road):* The southbound approach to this intersection is projected to operate at LOS F during the a.m. peak hour.
- *Intersection #22 (I-35 Northbound Ramps/Gardner Road):* This intersection is projected to operate at LOS E during the a.m. peak hour.

The indirect impact associated with Intersection #11 is considered to be significant, and potential mitigation measures are discussed in the *Mitigation Technical Report* (HDR 2008c). While Intersection #22 is predicted to operate below the acceptable LOS threshold in 2015, based on coordination with KDOT, the impact is not considered to be significant because the condition is predicted to be temporary and will be alleviated by the opening of the I-35/Waverly Road interchange by the end of 2015 or shortly thereafter.

[1] In the Proposed Action and Indirect Effects scenarios these intersections become OWSC due to road closures.

2015 Gardner IMF Operations plus Induced Development Freeway/Ramp Analysis

Table 3-23 summarizes the LOS analysis for freeways and ramps. Like the 2015 Gardner IMF Operations scenario, the analysis predicted an LOS E on northbound I-35 from US 56 to 151st Street in 2015 as well as at the associated US 56 eastbound on-loop to northbound I-35. The analysis also predicted levels or service below the desirable threshold in two additional areas:

- *I-35 Southbound, 151st Street to US 56*: This segment is projected to operate at LOS E; it is the reverse/complementary direction of the segment described above.
- *I-35 Southbound Off-Ramp to US 56*: This ramp is forecasted to operate at LOS E.

However, these four capacity issues would be anticipated to be addressed by planned improvements included in the MARC LRTP. Therefore, only minor adverse impacts are predicted to occur to freeway and ramp operation. If for some reason, the planned improvements to I-35 do not follow what is currently outlined in the LRTP, the 2015 traffic volumes would be near the LOS D/E threshold. Only minimal traffic diversion to the local and regional arterial street system in 2015 would be expected.

3.3.3 2030 Gardner IMF Operations plus Induced Development

2030 Gardner IMF Operations plus Induced Development Forecast Volumes
Under this scenario, the proposed Gardner IMF is projected to operate with 870,000 annual lifts and generate nearly 6,000 vpd, including approximately 563 during the a.m. peak hour and 388 during the p.m. peak hour. Based on reasonably foreseeable growth, the Logistics Park Kansas City is expected to occupy 2.86 million square feet (Crandall VS, 2008) and generate approximately 11,000 vpd, including 530 during the a.m. peak hour, and 716 during the p.m. peak hour (Table 3-24).

These trips were assigned to the study area roadways using procedures described earlier in this document and detailed in Appendix A.

Table 3-24: 2030 Gardner IMF Operations plus Induced Development Trip Generation

		AM Peak Hour			PM Peak Hour		
	Daily	in	out	total	in	out	total
IMF							
Trucks	3,121	68	103	171	120	94	214

Total	17,080	706	387	1,093	542	562	1,104

Note: Bobtails are not typically measured at existing IMFs. A conservative estimate was calculated to capture potential bobtail traffic. Actual bobtail trips are likely to be less than what has been projected as trips will be generated by

The 2030 Gardner IMF Operations plus Induced Development ADT and peak-hour forecasts are presented in Figures 3-23 and 3-24. Peak hour truck percentages are illustrated in Appendix C.

2030 Gardner IMF Operations plus Induced Development Geometry Assumptions
The base geometry assumptions for this scenario are identical to those of the 2030 Gardner Improved No Action scenario.

Figure 3-23: 2030 Gardner IMF Operations plus Induced Development ADTs

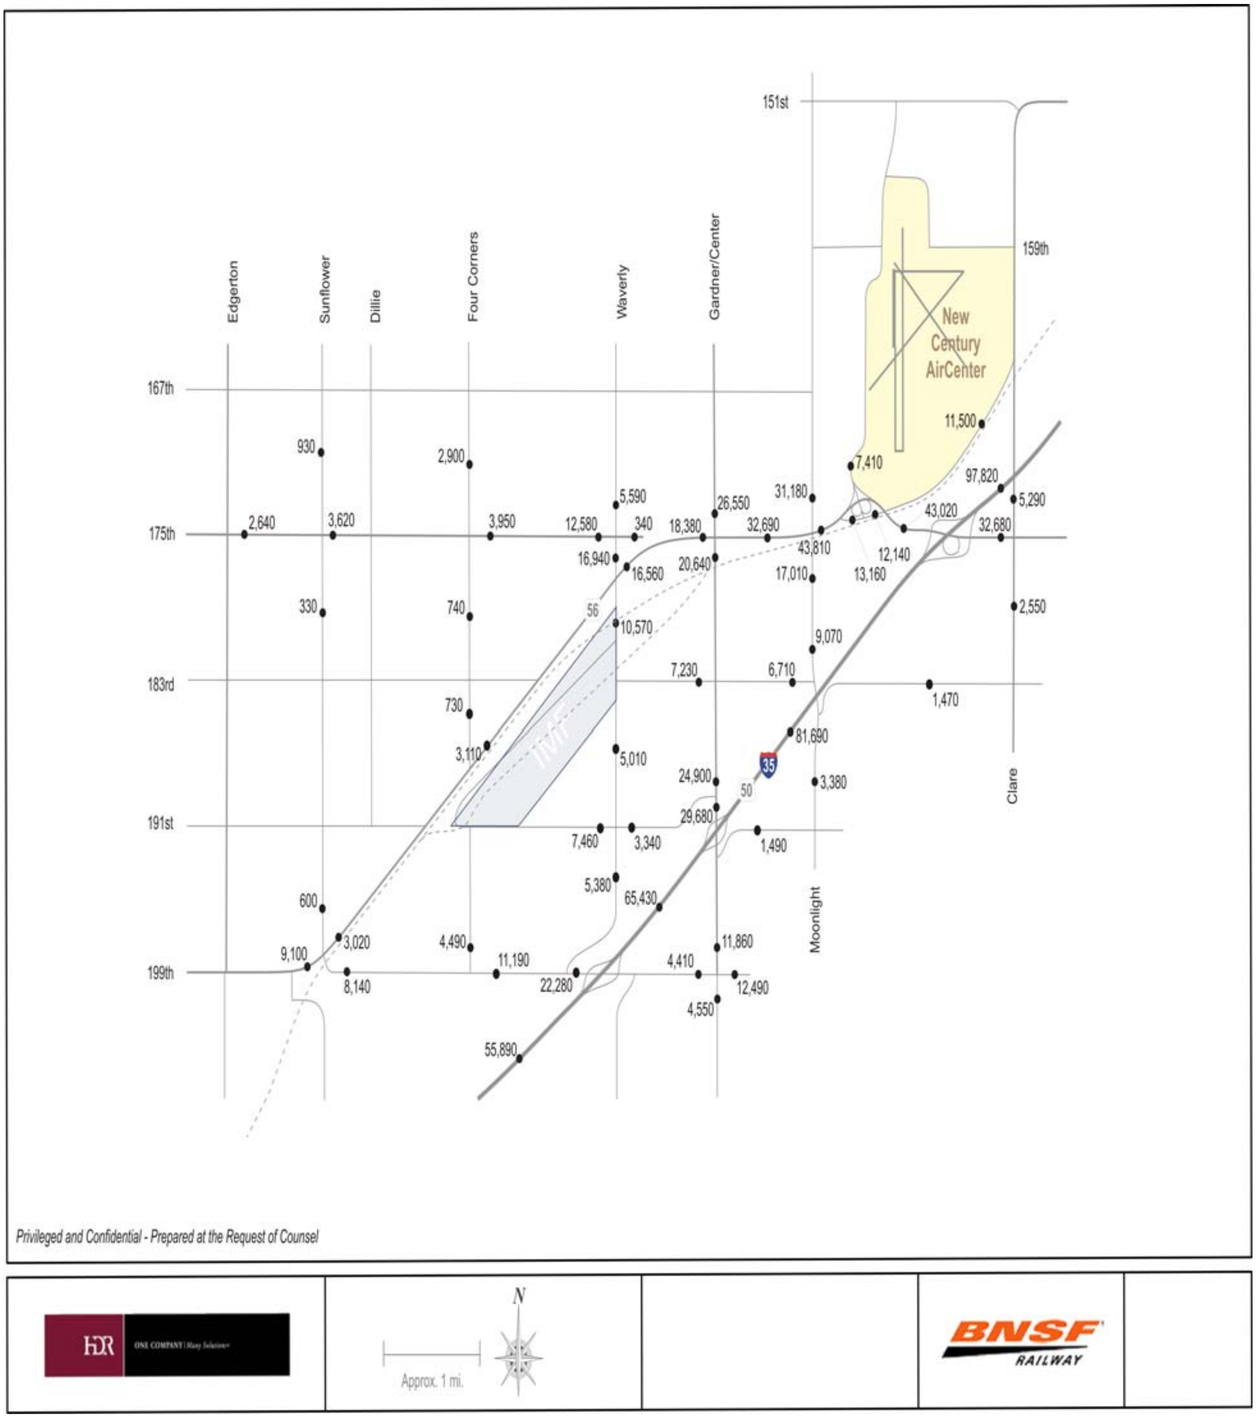

Figure 3-24: 2030 Gardner IMF Operations plus Induced Development Turning Movement Volumes

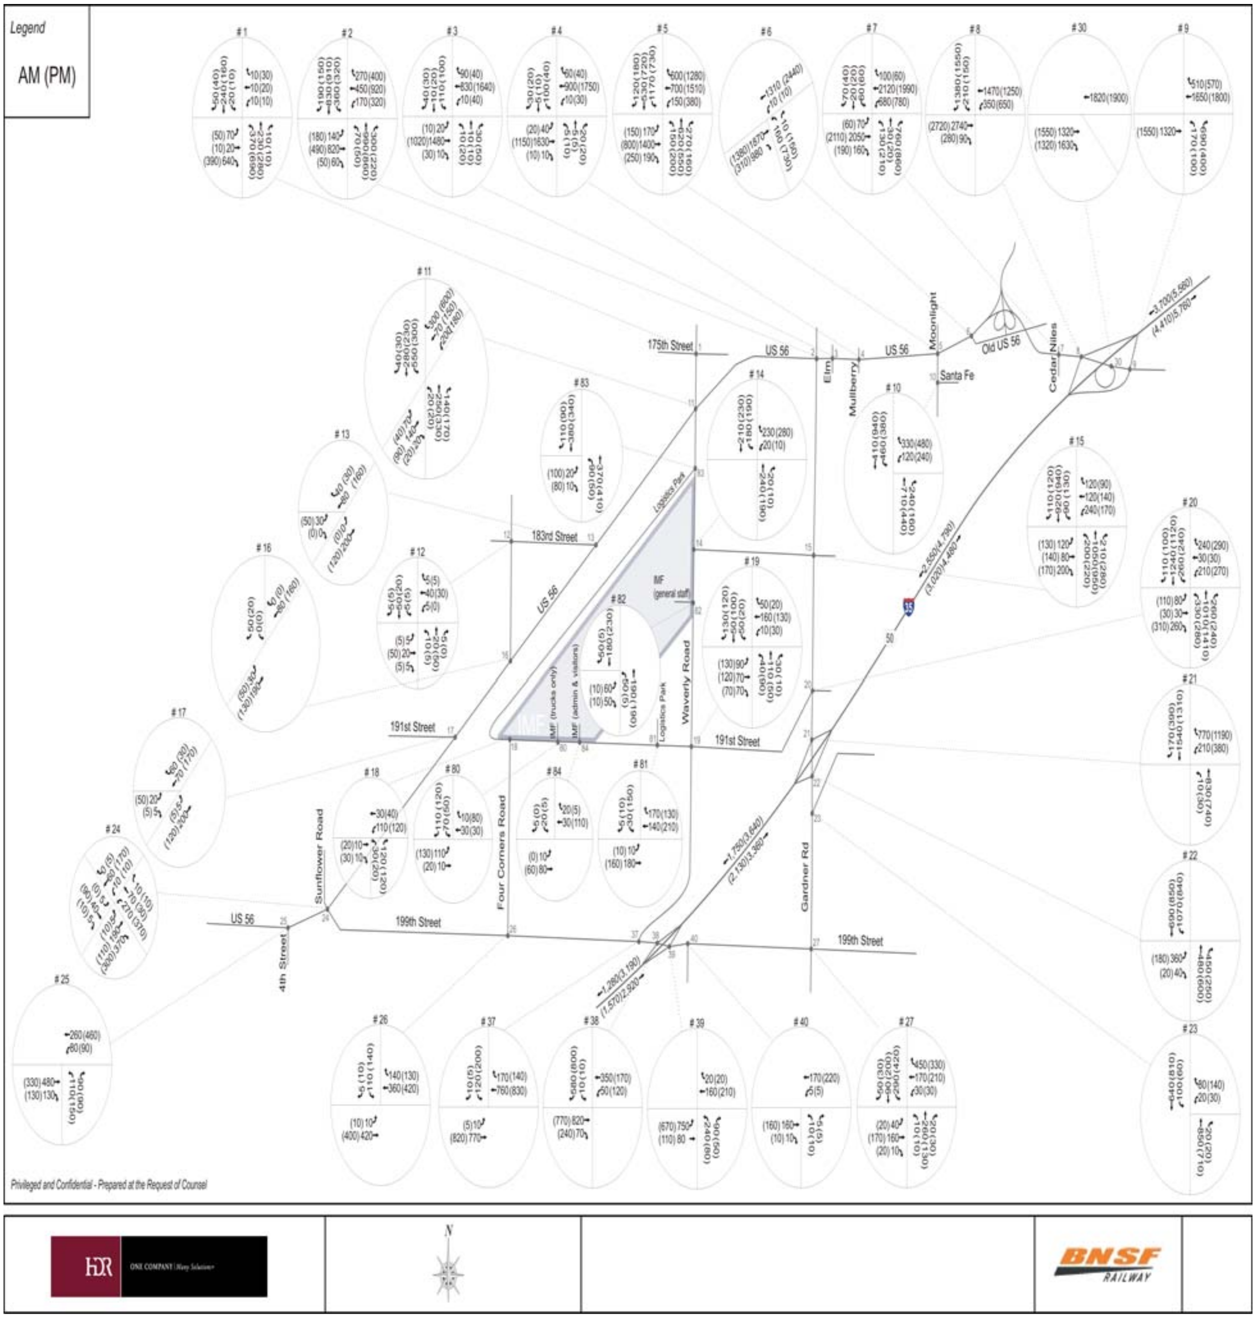

<u>2030 Gardner IMF Operations plus Induced Development Intersection Analysis</u>

Table 3-25 summarizes the results of the intersection analysis for this scenario. As the table indicates, the three intersections that were projected to operate below the acceptable LOS threshold under the Improved No Action scenario (5, 7, 8) are projected to continue to operate at the same LOS with the addition of the Proposed Action and indirect effects, with generally minor changes in delay that are not considered significant. The two intersections that were projected to operate below the acceptable LOS threshold under the 2030 Gardner IMF Operations scenario (26, 37) are projected to continue to experience levels of service below the acceptable threshold under this scenario; however, this is considered a moderate potential impact in 2030 and mitigation is not required.

In addition, LOS issues are projected at one other intersection:

- *Intersection 19 (191st Street/Waverly Road)*: The northbound approach to the intersection is projected to operate at LOS F during the p.m. peak hour. This year 2030 potential impact is considered moderate and would not require mitigation.

Table 3-25: 2030 Gardner IMF Operations plus Induced Development Study Intersection Analysis

2030 Gardner IMF Operations plus Induced Development Freeway/Ramp Analysis

Table 3-26 summarizes the LOS analysis for freeways and ramps. Like the 2030 Gardner IMF Operations scenario, the analysis predicted LOS E on northbound I-35 from US 56 to 151st Street, and the associated US 56 eastbound on-loop to northbound I-35. However, this scenario also shows a LOS below the acceptable threshold in one additional area:

- *I-35 Southbound, 151st Street to US 56*: This segment is projected to operate at LOS E (just exceeding the D/E threshold); it is the reverse/complementary direction of the segment previously described. It is fairly typical to widen freeway basic lanes symmetrically; thus, it would be reasonable to expect that in addressing the improvements needed in the 2030 No Action scenario (southbound), the northbound segment would also be widened. Therefore, it is not considered a significant impact

No capacity improvements for this area are currently programmed in the LRTP. However, because this area would fail under the No Action scenario, these LOS issues are not considered to be significant impacts from the Gardner IMF or Induced Development.

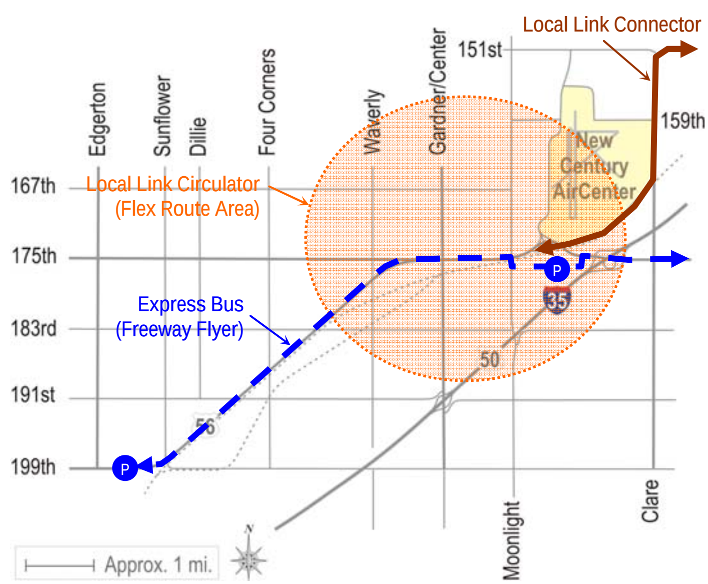
Bold indicates a LOS below the acceptable threshold.

3.3.4 Transit

Figure 3-25: Long-Term Planned Transit Service



With the addition of the 2.86 million square feet of warehousing associated with the Logistics Park Kansas City by 2015, it is expected that the demand for transit would increase somewhat over the Gardner IMF Operations Scenario. It is estimated that this new warehouse development would employ over 1,700 people. However, given the low-density development patterns required for modern warehouse space, and the two- and three-shift patterns often in use in these facilities, it may still be difficult to effectively and efficiently serve this development with transit. While transit service to the development could be pursued in the future as the development proceeded, it might not be practical in the near-term. However, given the proposal for a Gardner circulator bus route (Figure 3-25), it would be beneficial if planning for that route would consider any new Logistics Park Kansas City warehousing space. This planned circulator route presents a good opportunity for providing enhanced transportation options in the Gardner area. It may also be beneficial if Johnson County Transit considered providing reverse-commute transit service as part of its peak-period express service to the Gardner area (a.m. inbound to Gardner and p.m. outbound from Gardner). This could potentially be implemented with modest added cost and could increase accessibility for employees living in other parts of the metro area. However, neither of these planning considerations for transit is considered necessary as a consequence of development of the Logistics Park Kansas City.

3.3.5 Pedestrian/Bicycle

With the addition of the Logistics Park Kansas City, two potential areas of impact were considered: the potential pedestrian, bicycle, and trail activity or demand associated with the Logistics Park Kansas City development and the physical relationship of this development to existing and proposed pedestrian, bicycle, and trail facilities.

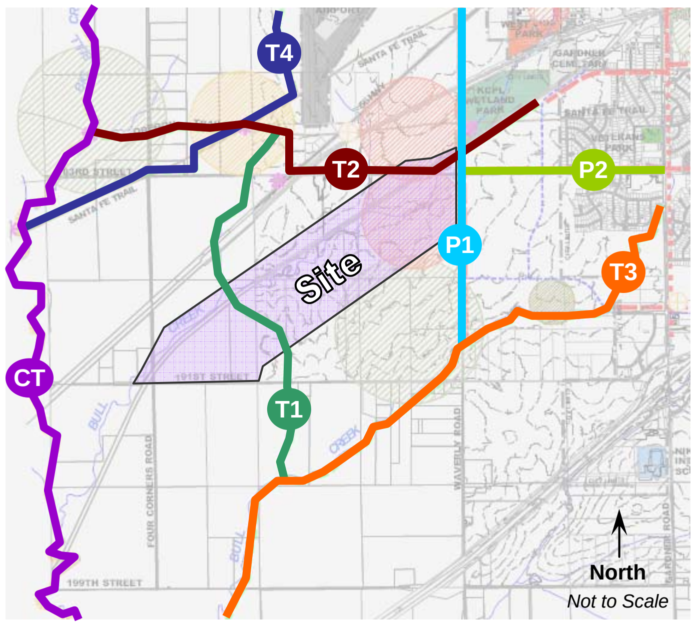
On opening day (2010), off-site pedestrian traffic associated with the Logistics Park Kansas City development is expected to be minimal. The primary reason for this is the long walk distances between the development and most residential or retail destinations. Following the roadways, the nearest subdivision entrance is over 2 miles from the assumed 2010 Indirect Effects development site and the nearest retail establishment is over 1.5 miles away. Second, the estimated total number of local employees on site at any one time in 2010 (for both the IMF and Logistics Park Kansas City) would still be fairly modest (between 250 and 430). A third reason is the off-peak two-shift/three-shift nature of intermodal and warehouse work. Approximately 80 percent of the BNSF employees would work 12-hour shifts, with shift changes at 7:00 a.m. and 7:00 p.m. The warehouse employee work schedule could be a one-, two-, or even three-shift schedule.

Pedestrian activity may increase in the future if new development were to occur within walking distance of the warehouse development, but given the nature and dispersion of the on-site activity, it is not expected to be a major mode for the site in the foreseeable future.

Bicycle activity is expected to be minimal for the same reasons that pedestrian activity is expected to be minimal. In the near term, any bicycle activity associated with the facility would be adult work-based trips and these trips could be accommodated on the planned paved roadways (or sidewalks on 191st Street). In the longer term, the new arterial pathways on Waverly Road and 183rd Street could also be available.

Regarding the impact on the existing and proposed facilities, while there are no existing facilities that would be physically impacted by the Logistics Park Kansas City development, it could affect some of the proposed future facilities in the area. However, the City of Gardner has indicated that it expects to initiate a new Master Plan for trails and pathways later this year (2008). The City expects major changes to the proposed trails and pathways in the vicinity of the Proposed Action and the Logistics Park Kansas City to avoid conflicts with these planned developments. Therefore, the potential impacts described below are expected to be resolved through the completion of the updated Master Plan. Figure 3-26 illustrates the trails.

Figure 3-26: Potential Future Trails



- *Gardner Trail 1 (T1)* - The north-south trail that would cut through the project site would also potentially conflict with the Logistics Park Kansas City development. It would need to be rerouted, shortened, or eliminated. There are other routing options as outlined previously in Section 3.2.6.
- *Gardner Trail 2 (T2)* – The east-west trail along 183rd Street would divide the intermodal site and would also potentially be in conflict with the Indirect Effects development. It would need to be rerouted, shortened, or eliminated as outlined in Section 3.2.6.
- *Gardner Trail 3 (T3)* – This trail would intersect Waverly Road just north of 191st Street and then continue southwest across 191st Street. It could potentially be in conflict with the Logistics Park Kansas City development. One rerouting option would be to modify the plan to show the trail following Waverly south to 191st Street and then 191st Street west to reconnect with the prior trail alignment.
- *Pathway on Waverly Road (P1)* - The proposed pathway along Waverly Road can still be implemented as planned. It would run along the edge of a portion of the Logistics Park Kansas City development. As mentioned in Section 3.2.6, there is ongoing coordination between the roadway planners and the City regarding if and where trail facilities are needed along both Waverly Road and 191st Street consistent with the update of the Master Plan.

3.3.6 At-Grade Rail-Highway Crossings and Delay

The Logistics Park Kansas City development would not alter the projected train volumes or speeds. It would, however, increase traffic volumes, mainly over the Waverly Road crossing. Thus, the number of vehicles actually delayed at the Waverly crossing (during the p.m. peak hour) would increase by 5 in 2010, 56 in 2015, and 78 in 2030 compared to the Proposed Action and Future Gardner IMF Operations scenarios. The average delay to all vehicles and the average delay to delayed vehicles, however, would change very little regardless of the year ($\pm$ 3 seconds or less). Therefore, only minor indirect impacts to crossing delay are anticipated.

3.3.7 Emergency Vehicle Access

The Logistics Park Kansas City development would not result in any additional road closures or rail re-alignments. Therefore, no significant impacts are expected to emergency vehicle response distances or response times in the area.

3.3.8 Circulation System

In the Gardner IMF Operations plus Induced Development Scenario, the local and regional connectivity in the vicinity of the Gardner IMF would not change substantially as there would be few major highway modifications. The volume of traffic on the local roadways (especially Waverly Road) would increase. This would further highlight the importance of Waverly Road as a north-south arterial in the area. It was assumed in the traffic modeling that the new service road (between the IMF and the BNSF mainline tracks to the north) would ultimately connect to 191st Street (near Four Corners). This connection would provide development on the service road north of the IMF with additional options for reaching the regional highway system because there would be two ways to access that development area. Consistent with the 2030 Proposed Action scenario, it was also assumed in the traffic modeling that through trucks would be restricted from using both 183rd Street and 191st Street/188th Street between Waverly Road and Gardner Road.

3.3.9 Roadway Design Considerations

The Logistics Park Kansas City development would increase traffic volumes on some of the area roadways as outlined previously. In 2010 and 2015, much of the truck traffic would use Waverly Road and 191st Street to access Gardner Road and I-35. Both Waverly Road and 191st Street are anticipated to be upgraded as part of the Proposed Action in advance of the Logistics Park Kansas City development and in accordance with applicable design standards. Improvements to Gardner Road near I-35 are being made by KDOT as previously discussed. In the 2010 and 2015 Scenarios, the majority of IMF and Logistics Park Kansas City truck traffic are forecasted to use 191st Street and Gardner Road to travel to and from I-35. For example, in 2015, 202 out of 247 p.m. peak hour trucks leaving the IMF and Logistics Park Kansas City area are forecasted to use this route (over 81 percent)[2]. This would minimize any potential near-term effects on other local roadways.

Because the location of a new interchange has not been determined by KDOT, this analysis assumed the CARNP location for an interchange. By 2030, the new I-35 interchange at 199th Street and Waverly Road between the City of Gardner and the City of Edgerton was forecasted to attract the vast majority of IMF and Logistics Park Kansas City truck traffic. However, the trucks would use a combination of the new Waverly Road connection between 191st Street and 199th Street and the Four Corners connection to 199th Street to access this interchange. Also, 199th Street is anticipated to be improved (as called for in the CARNP plan), in response to area/corridor development needs as mentioned in the No Action Scenario. Therefore, Four Corners Road may be the one roadway in the 2030 Scenario that could experience truck volumes for which it was not designed. However, given the closure of Four Corners north of 191st Street, non-IMF and non-Logistics Park Kansas City traffic on that roadway would be minimal. One other point that should be mentioned is that while this analysis assumes that the new I-35 interchange

[2] As previously discussed, the 2015 analysis does not include the new interchange. However, it is included in the 2030 analysis.

will not be in service by 2015, it could be available by then or a short time after. When it is in service, the traffic patterns are expected to shift as explained for 2030, although 2015 volumes would be lower than the volumes predicted for 2030.

By 2030, the Logistics Park Kansas City truck routing is forecasted to shift to the new interchange.

Conflicts between school traffic and the combined Logistics Park Kansas City and IMF truck traffic are not anticipated because of the low volume of trucks from these sources traveling in front of the local schools. For example, in 2015 two trucks are projected to use Gardner Road south of I-35 (in the vicinity of the Nike Elementary School) during the 7:00 to 8:00 a.m. hour. On Waverly Road north of US 56, in 2015 two trucks are projected during this a.m. peak hour. No IMF trucks are projected to use US 56 just west of Waverly and 29 trucks are projected on US 56 east of Waverly road during the a.m. peak hour.

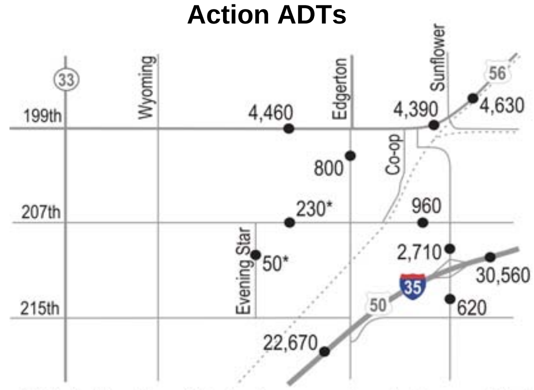
3.3.10 Construction Traffic

Construction of the Logistics Park Kansas City would begin sometime near the beginning of the Proposed Action construction activity. The first building would be completed within 12 to 24 months of the start of the Proposed Action depending on the exact start time, building size, location, market factors, and other key parameters. Construction of the building would include both the building itself and associated site improvements (such as parking, drainage, utilities, and on-site roadways). Construction staging areas would likely be on site. After construction of the first building, additional buildings are anticipated over the next five years. Therefore, construction activities would be beginning and ending at various locations over the course of this time period. It is not currently known how much construction traffic would be generated at any one time over the course of the construction of the Logistics Park Kansas City. A traffic management plan would address the issue of site access and egress including haul routes to and from the site as necessary.

3.4 Direct Effects – Wellsville North

This section includes traffic analysis of the Wellsville North Alternative located further to the south and west of the Gardner project site, near the City of Wellsville. The operational analysis uses the same methodology, but focuses on a different set of intersections that partially overlap the Gardner traffic study area (as previously discussed in Section 2.2). Detailed operational analysis sheets for intersections and freeway facilities are included in Appendix G.

Figure 3-27: 2010 Wellsville North No Action ADTs



*Estimated based on existing turning movement counts plus a growth factor

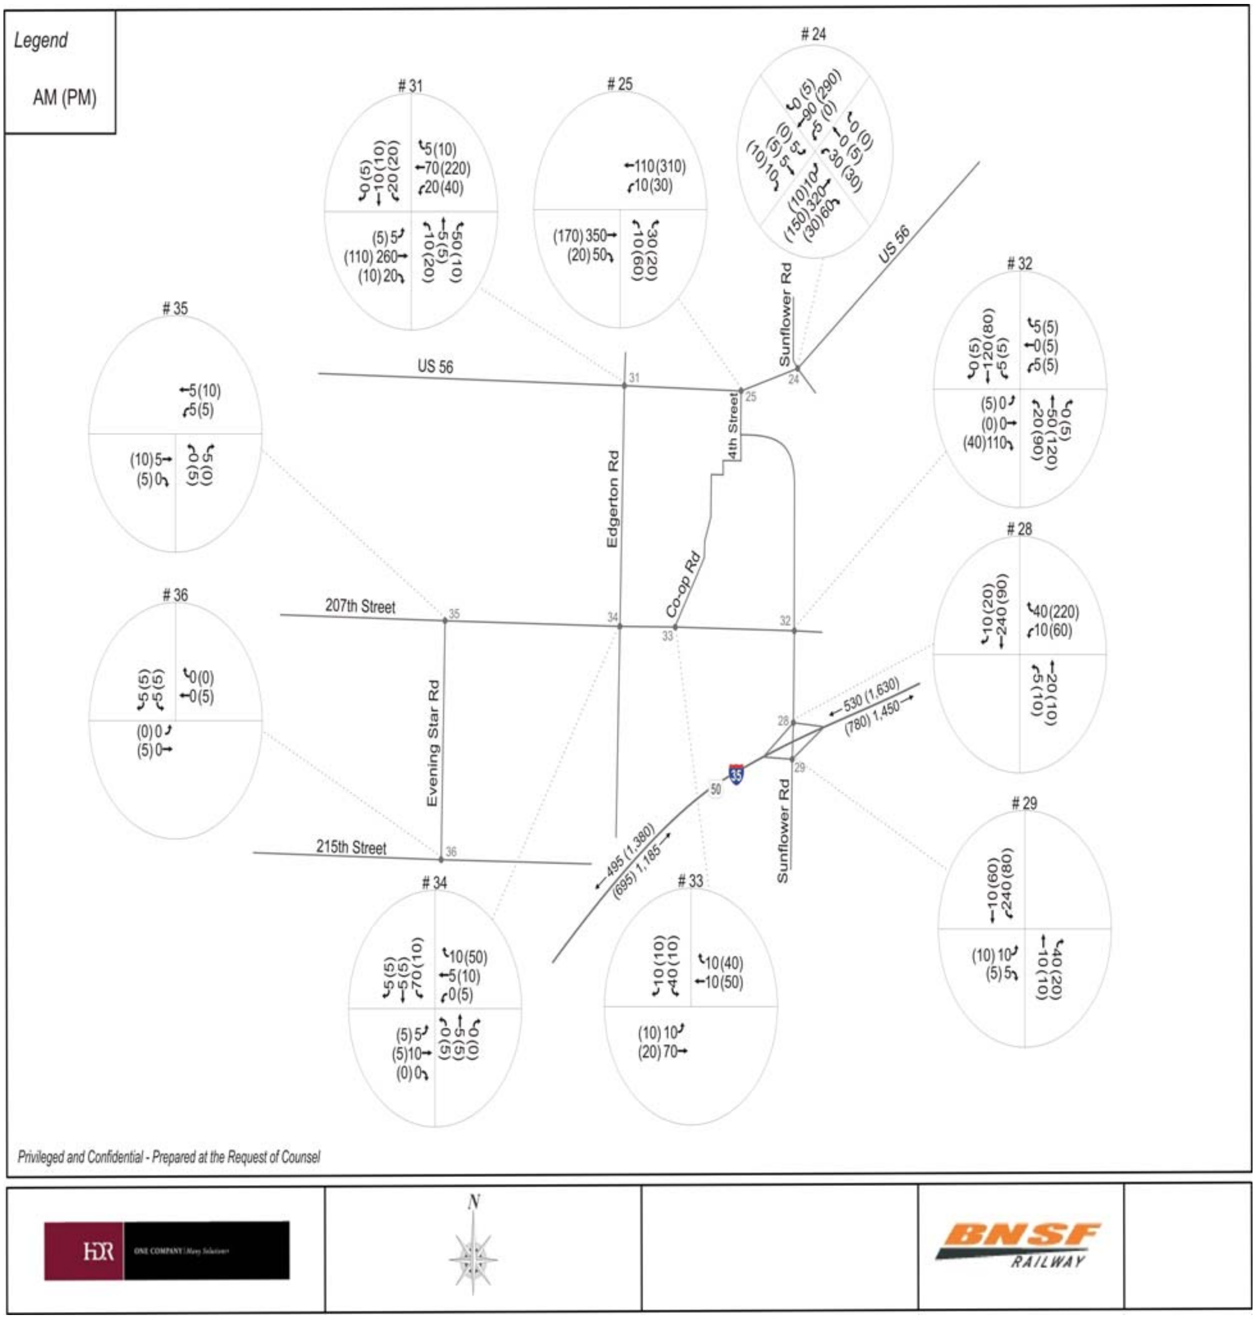
3.4.1 2010 Wellsville North No Action

2010 Wellsville North No Action Forecast Volumes

As with the Proposed Action, the 2010 Wellsville North Alternative No Action scenario is a near-term scenario for comparing opening day for this alternative. It assumes modest near-term traffic growth consistent with historical growth in the area. Based on KDOT traffic count data, and consistent with the recently completed I-35 Gardner BIA Study, a growth rate of 2.8 percent per year was assumed for intersections and a growth rate of approximately 3.2 percent per year was assumed for the I-35 mainline. These growth rates were applied to the existing (2008) volumes.

The resulting 2010 No Action ADT volumes and peak-hour turning-movement volumes are shown in Figures 3-27 and 3-28. The volumes are rounded, reflecting that they are forecasts. The peak hour truck percentages are illustrated in Appendix C.

Figure 3-28: 2010 Wellsville North No Action Turning Movement Volumes



<u>2010 Wellsville North No Action Geometry Assumptions</u>
Section 3.1.1 describes a set of near-term improvements that are planned in the Gardner study area, as well as "Improved No Action" improvements that could reasonably be expected to occur to accommodate growth in the area not associated with an IMF at the Wellsville North site (i.e., 2010 Gardner No Action scenario). Of these improvements, only two overlap with the Wellsville North study area, including signalization and associated improvements at *Intersections #8 (US*

56/I-35 SB Ramps) and *#9 (US 56/I-35 NB Ramps)*. No improvements beyond these were assumed for the 2010 Wellsville North Improved No Action scenario.

2010 Wellsville North No Action Intersection Analysis

A total of 18 intersections were examined using the projected 2010 No Action traffic volumes and the Improved 2010 No Action network assumptions described previously in this section. The results of this analysis are shown in Table 3-27. In this scenario, all study intersections are projected to operate at LOS C or better.

Notes: pc/mi/ln – passenger cars per mile per lane, LOS – Level of Service

The 2010 Wellsville North No Action freeway analysis assumes the forecasted volumes presented in Figure 3-28 and the current mainline and ramp geometry. The resulting operational analysis (for both mainline and ramp junctions) is summarized in Table 3-28. As the table indicates, all locations are forecasted to operate at an acceptable LOS of D or better during both peak hours.

3.4.2 2010 Wellsville North Alternative

2010 Wellsville North Alternative Forecast Volumes

To develop traffic forecasts for this analysis, the same intermodal trip generation assumptions were applied that were used for the 2010 Proposed Action scenario, resulting in 2,900 vpd, including 273 during the a.m. peak hour and 185 during the p.m. peak hour. Traffic was distributed and assigned to the network using the same methodology used for the 2010 Proposed Action scenario (Appendix A).

The resulting 2010 Wellsville North Alternative ADT volumes and peak-hour turning-movement volumes are shown in Figures 3-29 and 3-30. The volumes are rounded, reflecting that they are forecasts. The peak hour truck percentages are illustrated in Appendix C.

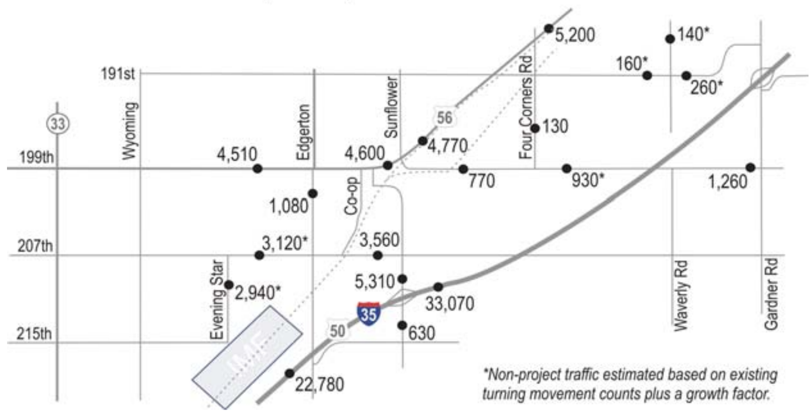

Figure 3-29: 2010 Wellsville North Alternative ADTs

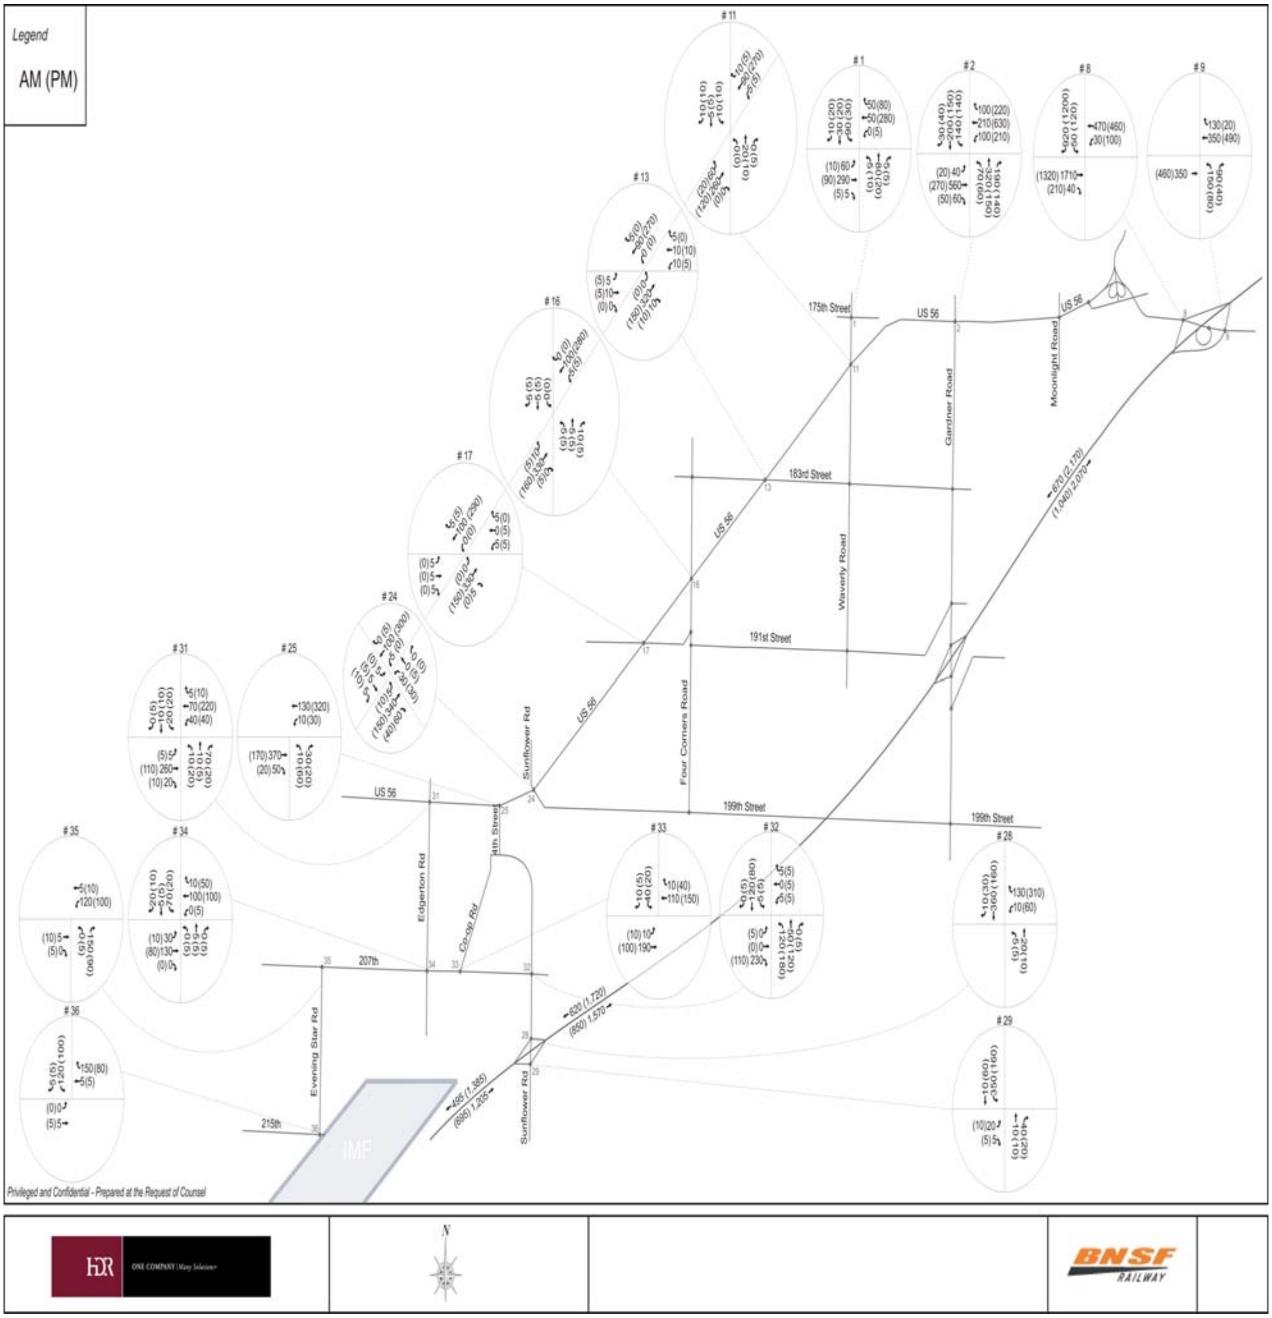
2010 Wellsville North Alternative Geometry Assumptions

For purposes of analyses of the Wellsville North Alternative, it was assumed that certain improvements would be necessary to be able to accommodate construction and operation of an IMF at the Wellsville site. These assumptions include upgrading both Evening Star Road and 207th Street to provide needed pavement sections and widths to support the intermodal truck traffic. In addition, improvements at Intersections 8 and 9 were assumed to be constructed without the IMF (“Improved No Action”).

Figure 3-30: 2010 Wellsville North Alternative Turning Movement Volumes



2010 Wellsville North Alternative Intersection Analysis

The results of the intersection analysis for this scenario are summarized in Table 3-29. As the table indicates, all intersections analyzed for the Wellsville North scenario are projected to continue to operate at LOS D or better. Therefore, minor impacts to intersections are anticipated.

For one and two-way STOP-controlled intersections the delay and LOS for the worst approach is shown.

2010 Wellsville North Alternative Freeway/Ramp Analysis

Table 3-30 summarizes the results of the freeway analysis for this scenario. As the table indicates, all freeway segments and ramps analyzed for the Wellsville North scenario are projected to continue to operate at LOS C or better with the Wellsville North Alternative. Therefore, minor impacts are predicted.

Table 3-30: 2010 Wellsville North Alternative Freeway/Ramp Analysis

3.5 Indirect Effects – Future Wellsville North IMF Operations

3.5.1 2015 Wellsville North No Action

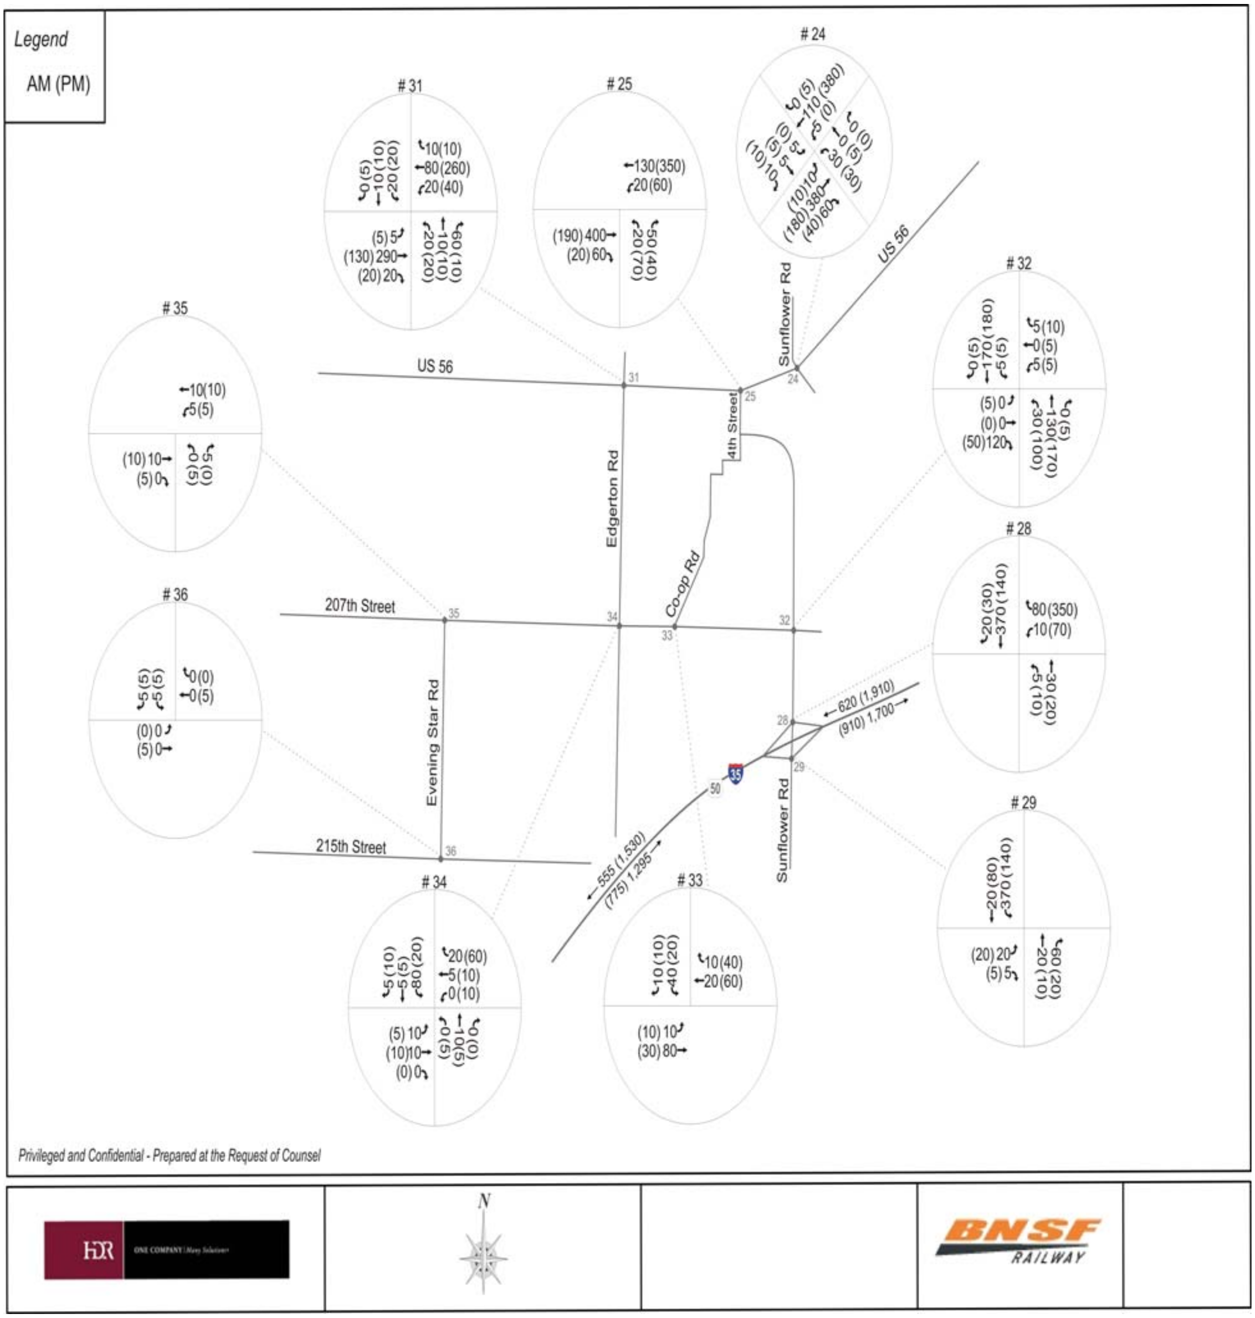
<u>2015 Wellsville North No Action Forecast Volumes</u>
As with the analysis of the Proposed Action, the 2015 Wellsville North Alternative scenario is a near-term scenario for comparing No Action conditions with those of the Wellsville North Alternative five years after opening day. It assumes modest near-term traffic growth consistent with historical growth in the area. Based on KDOT count data, and consistent with the recently completed I-35 Gardner BIA Study, a growth rate of 2.8 percent per year was assumed for intersections and a growth rate of approximately 3.2 percent per year was assumed for the I-35 mainline. These growth rates were applied to the existing (2008) volumes.

Figure 3-31: 2015 Wellsville North No Action ADTs

The resulting 2015 No Action ADT volumes and peak-hour turning movement volumes are illustrated in Figures 3-31 and 3-32. Peak-hour truck percentages are illustrated in Appendix C.

<u>2015 Wellsville North No Action Geometry Assumptions</u>
The 2015 Wellsville North No Action geometry assumptions are identical to those of the 2010 Wellsville North Improved No Action scenario (signalization and associated improvements at Intersections 8 and 9).

Figure 3-32: 2015 Wellsville North No Action Turning Movement Volumes



<u>2015 Wellsville North No Action Intersection Analysis</u>

Table 3-31 summarizes the results of the intersection analysis for this scenario. As Table 3-31 indicates, all study intersections are projected to operate at LOS C or better. Detailed intersection analysis sheets for the Wellsville North No Action scenarios are included in Appendix G.

Table 3-31: 2015 Wellsville North Improved No Action Study Intersection Analysis

<u>2015 Wellsville North No Action Freeway/Ramp Analysis</u>

The 2015 Wellsville North No Action freeway analysis assumes the forecasted volumes presented in Figure 3-32 and the current mainline and ramp geometry. The resulting operational analysis (for both mainline and ramp junctions) is summarized in Table 3-32. As the table indicates, all locations are fore-casted to operate at an acceptable LOS of C or better during both peak hours. Detailed freeway analysis sheets for the Wellsville North No Action scenarios are included in Appendix G.

Table 3-32: 2015 Wellsville North No Action Freeway/Ramp Analysis

3.5.2 2015 Wellsville North Alternative

<u>2015 Wellsville North Alternative Forecast Volumes</u>
To develop traffic forecasts for this scenario, the same intermodal trip generation assumptions were applied that were used for the 2015 Gardner IMF Operations scenario, resulting in nearly 3,500 vpd, including 335 during the a.m. peak hour and 222 during the p.m. peak hour. Traffic was distributed and assigned to the network using the same methodology used for the 2015 Gardner IMF Operations scenario (Appendix A).

The resulting 2015 Wellsville North Alternative ADT volumes and peak-hour turning-movement volumes are shown in Figures 3-33 and 3-34. The volumes are rounded, reflecting that they are forecasts. Peak hour truck percentages are illustrated in Appendix C.

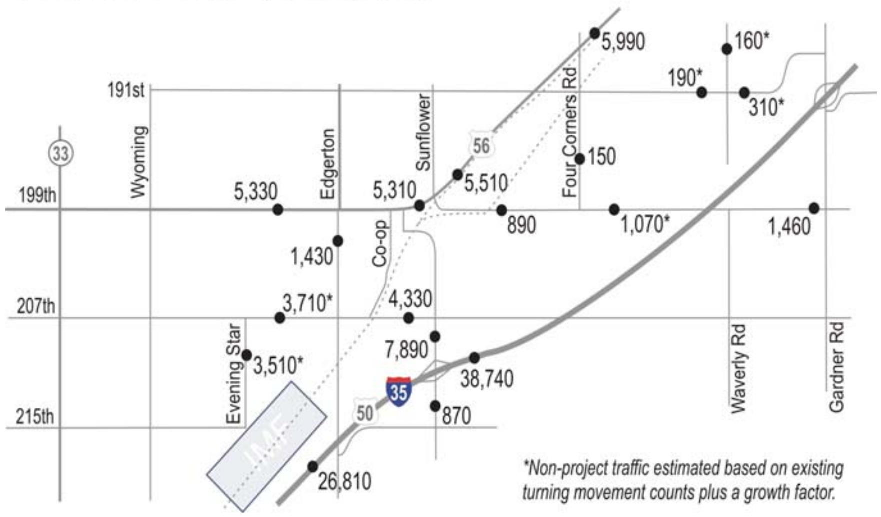

Figure 3-33: 2015 Wellsville North Alternative ADTs

<u>2015 Wellsville North Alternative Geometry Assumptions</u>
For purposes of analyses of the Wellsville North Alternative, it was assumed that certain improvements would be necessary to be able to accommodate construction and operation of an IMF at the Wellsville site (similar to the 2010 scenario). These assumptions include upgrading both Evening Star Road and 207th Street to provide needed pavement sections and widths to support the intermodal truck traffic. In addition, improvements at Intersections 8 and 9 were assumed to be constructed without the IMF ("Improved No Action").

<u>2015 Wellsville North Alternative Intersection Analysis</u>
Table 3-33 summarizes the results of the intersection analysis for this scenario, in comparison to the Wellsville North No Action scenario. Detailed intersection analysis sheets for the Future Wellsville North Alternative IMF Operations scenarios are presented in Appendix G. As the table indicates, the eastbound approach to Intersection 29 (I-35 Northbound Ramps/Sunflower Road) is forecasted to operate at LOS E during the a.m. peak hour. Potential mitigation measures to address this significant impact are discussed in the *Mitigation Technical Report* (HDR, 2008c).

<u>2015 Wellsville North Alternative Freeway/Ramp Analysis</u>
The 2015 Wellsville North Alternative freeway analysis assumes the forecasted volumes presented in Figure 3-34 and the current mainline and ramp geometry. The resulting operational analysis (for both mainline and ramp junctions) is summarized in Table 3-34 (Detailed freeway facility analysis sheets for the Future Wellsville North Alternative IMF Operations scenarios are presented in Appendix G). As the table indicates, all locations are forecasted to operate at an acceptable LOS of D or better during both peak hours. Therefore, the Wellsville North Alternative is not anticipated to impact freeway segments or ramps.

3.5.3 2030 Wellsville North No Action

2030 Wellsville North No Action Forecast Volumes

Like the 2030 Gardner No Action scenario, the 2030 Wellsville North No Action scenario is a long-term scenario for comparing No Action and Wellsville North Alternative conditions based on a 20-year time horizon from opening year. The forecasts developed for this scenario were developed using a combination of the Olathe regional travel demand model (at its southwestern fringe), growth factors, and known growth plans in Edgerton. The assumptions and the forecasting process are presented in detail in Appendix A.

As in the 2030 Gardner scenarios, the majority of the study segments are projected to experience appreciable traffic growth in the 2030 Wellsville North No Action scenario. Figure 3-35 illustrates the forecasted ADTs for this scenario; Figure 3-36 illustrates the forecasted turning movements. Peak hour truck percentages are illustrated in Appendix C.

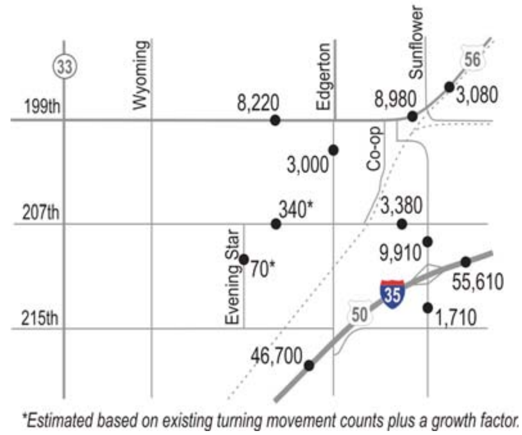

Figure 3-35: 2030 Wellsville North No Action ADTs

2030 Wellsville North No Action Geometry Assumptions

In addition to the improvements included in the 2030 Gardner No Action scenario, the Wellsville North No Action roadway network geometry includes a number of assumed enhancements to attempt to provide sufficient capacity for the projected 2030 No Action traffic. This includes signalization of both I-35/Sunflower Road ramps (Intersections #28 and 29) and conversion of intersection #31 (199th Street/Edgerton Road) to all-way stop control.

2030 Wellsville North No Action Intersection Analysis

The intersection analysis is summarized in Table 3-35. As the table indicates, two intersections are forecasted to operate at LOS E or worse under this scenario:

- *Intersection #8 (I-35 Southbound Ramps/US 56*): As in the Gardner No Action scenario, this intersection is projected to operate at LOS F during both peak hours. As described under the Gardner No Action scenario, the forecasts indicate that US 56 will need to be widened to three basic lanes in each direction by 2030.
- *Intersection #32 (207th Street/Sunflower Road):* The westbound approach is forecasted to operate at LOS E during both peak hours. The failing movement (left turns) is too small (five vehicles or less) to warrant improvements.

These long-term potential impacts are not related to an IMF at the Wellsville site.

2030 Wellsville North No Action Freeway/Ramp Analysis

The operational analysis (for both mainline and ramp junctions) is summarized in Table 3-36. As the table indicates, all locations are forecasted to operate at an acceptable LOS of D or better during both peak hours.

3.5.4 2030 Wellsville North Alternative

<u>2030 Wellsville North Alternative Forecast Volumes</u>

Since essentially the entire study area is outside the OTM, an alternative methodology was used to assign the traffic from the Wellsville North Alternative to the surrounding roadway network. The methodology, described in more detail in Appendix A, involved the use of the TRAFFIX software and the development of paths and distribution assumptions based on knowledge of existing and expected travel patterns in the study area.

The resulting 2030 Wellsville North Alternative ADT volumes and peak-hour turning movement volumes are illustrated in Figures 3-37 and 3-38. The peak hour truck percentages are presented in Appendix C.

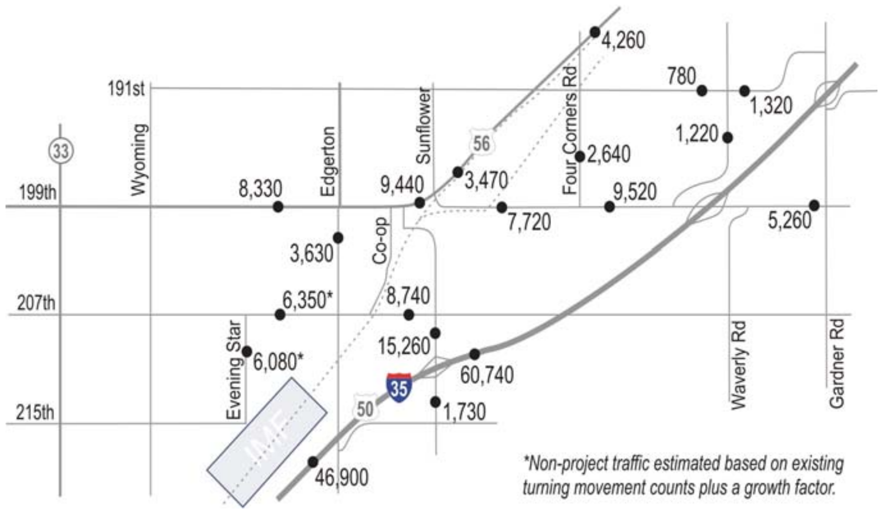

Figure 3-37: 2030 Wellsville North Alternative ADTs

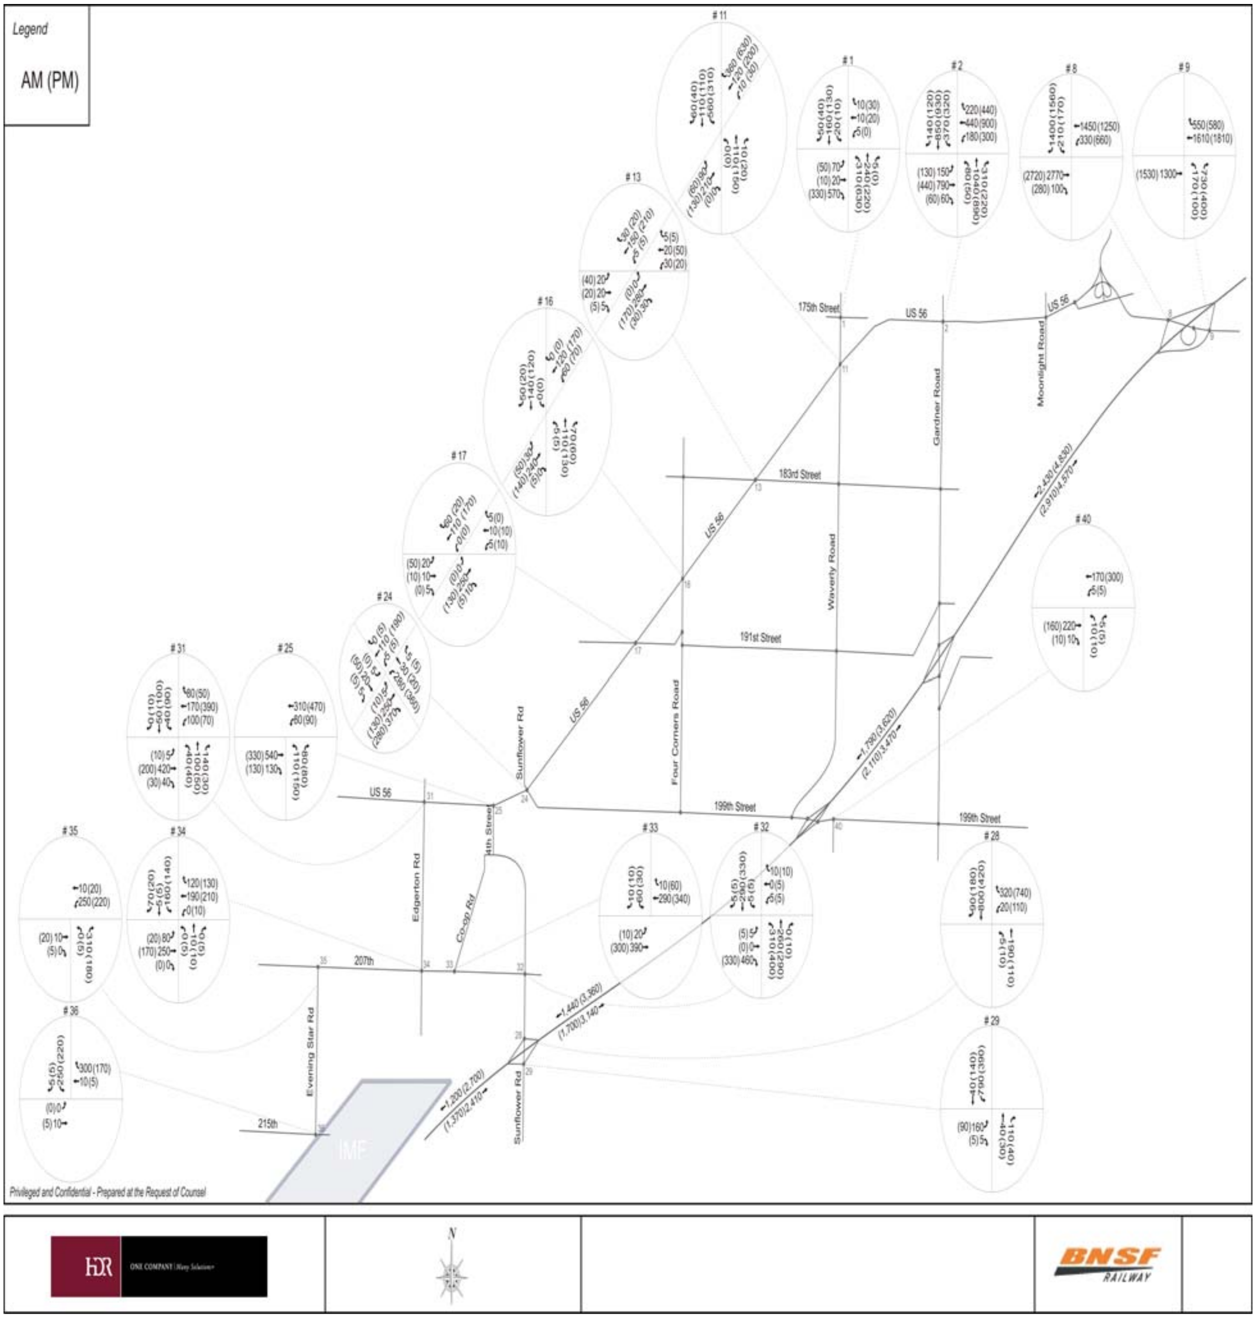
<u>2030 Wellsville North Alternative Geometry Assumptions</u>

In addition to the improvements included in the 2030 Gardner No Action scenario, the Wellsville North Alternative roadway network geometry assumptions include a number of enhancements to attempt to provide sufficient capacity for the projected 2030 Wellsville North Alternative traffic. This includes signalization of both I-35/Sunflower Road ramps (Intersections #28 and 29) and conversion of intersection #31 (199th Street/Edgerton Road) to all-way stop control (all part of the No Action Scenario), in addition to upgrades to Evening Star Road and 207th Street to provide needed pavement sections and widths to support IMF truck traffic.

Figure 3-38: 2030 Wellsville North Alternative Turning Movement Volumes



2030 Wellsville North Alternative Intersection Analysis

The results of the 2030 Wellsville North Alternative intersection analysis are shown in Table 3-37. Intersections #8 and #32 were predicted to operate at unsatisfactory levels under the No Action scenario and would also operate at unsatisfactory LOS F with the Wellsville North Alternative. Intersection #8 (I-35 Southbound Ramps/US 56) is projected to operate at LOS F during both peak hours. Given that the forecasted delay increases are modest, this condition could be improved to acceptable levels by improvements needed with the No Action scenario. The eastbound and westbound approaches at Intersection #32 (207^{th} Street/Sunflower Road) are also forecasted to operate at LOS F during both peak hours. As with the No Action scenario, the failing left turn movements are too small (five vehicles or less) to be considered a significant impact of the project.

As Table 3-37 indicates, four other study intersections are forecasted to operate unacceptably under this scenario:

- *Intersection #28 (I-35 Southbound Ramps/Sunflower Road)*: This intersection is projected to operate at LOS F during the p.m. peak hour.
- *Intersection #29 (I-35 Northbound Ramps/Sunflower Road):* This intersection is projected to operate at LOS F during the a.m. peak hour.
- *Intersection #34 (207^{th} Street/Edgerton Road):* This intersection is forecasted to operate at LOS E during the a.m. peak hour.
- *Intersection #36 (215^{th} Street/Evening Star Road):* The southbound approach is forecasted to operate at LOS E during the a.m. peak hour. Reconfiguring the intersection to make this a free movement would eliminate the operational issue.

Impacts to Intersection #28 and Intersection #29 would be considered significant should they occur as they are located on state or major routes. Potential mitigation measures are discussed in the *Mitigation Technical Report* (HDR, 2008c). However, impacts to Intersection #34 and Intersection #36 would be considered moderate should they occur, and would not require project-related mitigation.

2030 Wellsville North Alternative Freeway/Ramp Analysis

The resulting analysis (for both mainline and ramp junctions) is summarized in Table 3-38. As the table indicates, all locations are forecasted to operate at an acceptable LOS of D or better during both peak hours. Therefore, only minor impacts are anticipated.

Table 3-38: 2030 Wellsville North Alternative Freeway/Ramp Analysis

3.5.5 Transit

<u>No Action</u>
In the No Action scenario, no new transit service is expected to be provided to the Wellsville North Alternative project site in either the short or long-term. However, the Regional Transit Plan (Smart Moves) includes long-term plans for extending-peak period bus service to the City of Edgerton.

<u>Wellsville North Alternative</u>
As with the Gardner project site, two types of potential transit service impacts are evaluated here: 1) increased demands on existing or planned service; and 2) demands for new service to serve the Wellsville North Alternative.

None of the employees are expected to use bus transit service on opening day as there is currently no transit service in the vicinity of the site. In the future, if the transit plans envisioned for the area are implemented, the peak-period service would extend south on US 56 to Edgerton, but it would be unlikely to serve the intermodal site directly. It may also have limited (or no) frequency, especially during the off-peak intermodal shift-change periods.

As described for the Proposed Action, the demand on any transit service related to an intermodal site associated with the Wellsville North Alternative is expected to be minimal. One reason for this is that the off-peak, two-shift/three-shift nature of the work would make using transit for both trip ends difficult. For example, approximately 80 percent of the employees are expected to work a 12-hour two-shift schedule with employees either starting or ending a shift at 7:00 p.m., a time period that typically has low-frequency bus service in low-density areas. In addition, the lack of regional service coinciding with the shift-change peaks would make it impractical for many employees to use transit.

In addition to the issues of shift-change schedules, bus routes/frequencies, and stop locations, there is the larger issue of overall demand and the provision of bus service to a low-density employment site. The intermodal site would have a low employment density with approximately 70 local employees on site during any one shift in 2010 (135 in 2030). This would result in an employment density of approximately one employee per 7.0 acres in 2010 and one employee per 3.5 acres in 2030. These employment densities are not typically consistent with the provision of regular scheduled bus service. In fact, service to these types of sites can have considerable cost, travel time, and delay implications for the service provider and other riders.

Therefore, as outlined above, no impacts are expected to the current or proposed transit service due to increased demand and no significant demand for new bus service is anticipated.

3.5.6 Pedestrian/Bicycle

<u>No Action</u>
In the No Action scenario, there are no major known planned changes to the pedestrian and bicycle facilities in the vicinity of the Wellsville North project site (including sidewalks, trails, or bike routes/paths).

<u>Wellsville North Alternative</u>
As with the Gardner project site, in the near term, pedestrian traffic to and from the Wellsville North Alternative project site is expected to be minimal. The primary reason for this is the long walk distances between the site and most residential or retail destinations. The nearest subdivision entrance is over two miles from the main gate. Second, as outlined previously, the number of on-site employees would be modest (under 70 on opening day and approximately 135 in 2030). A third reason is the off-peak two-shift/three-shift nature of the work. As mentioned in the transit section, approximately 80 percent of the on-site employees would work 12-hour shifts

with shift changes at 7:00 a.m. and 7:00 p.m. This would mean that employees would have to walk after dark during a portion of the year.

Pedestrian activity may increase in the future if new development would occur within walking distance of the project, but given the number of employees and the nature and dispersion of the on-site activity, it is not expected to be a major mode of transportation related to a project at the site. The pedestrian activity resulting from the Wellsville North Alternative could be accommodated on the 8-foot shoulders that would be included in the upgrades to Evening Star Road and 207th Street. The provision of paved shoulders (8-foot minimum) is considered important given the volume of truck traffic forecasted for these roadways.

Bicycle activity is expected to be minimal for the same reasons that pedestrian activity is expected to be minimal. Special provision of bicycle routes or lanes is not typically necessary for this type of land use. Any bicycle activity associated with the facility would be adult work-based trips and these trips could be accommodated on the planned paved roadways.

Regarding the impact on the existing and proposed facilities, there are no existing or future pedestrian or bicycle facilities that would be physically impacted by the Wellsville North Alternative.

3.5.7 At-Grade Rail-Highway Crossings and Delay

<u>No Action</u>
In the No Action Scenario, train volumes and lengths would continue to increase over time, leading to increased blocked times[3] and increased vehicular delay at all of the at-grade highway-rail crossing locations. The blocked times and delay are expected to be similar to those presented previously in the Gardner No Action scenario.

<u>Wellsville North Alternative</u>
With the Wellsville North Alternative, there would have to be a number of changes to the current at-grade crossings in the area (see Figure 2-14). They include from south to north:

- *Main Street in Wellsville* – Grade-Separated
- *223rd Street* – Grade-Separated
- *215th Street* – Closed
- *Edgerton Road* – Grade-Separated
- *207th Street* – Grade-Separated
- *E. Nelson Street* – At-Grade
- *199th Street* – At-Grade

Thus, in the Wellsville North Alternative scenario, a total of five at-grade crossings would be eliminated through grade separation or closure. The remaining two at-grade crossings would experience increased blocked time and delay. However, similar to the situation at Moonlight Road in the Proposed Action scenario, these two locations would actually have fewer trains than in the No Action scenario because they are located north of the site. While the maximum delay time would likely increase as was shown for the Proposed Action, it is not expected that the total increase in average blocked time and delay would be significant (in fact, it could decrease). Therefore, no significant impacts are predicted.

[3] Blocked time includes both the train occupancy time and the time of the flashing light or gate down.

3.5.8 Emergency Vehicle Access

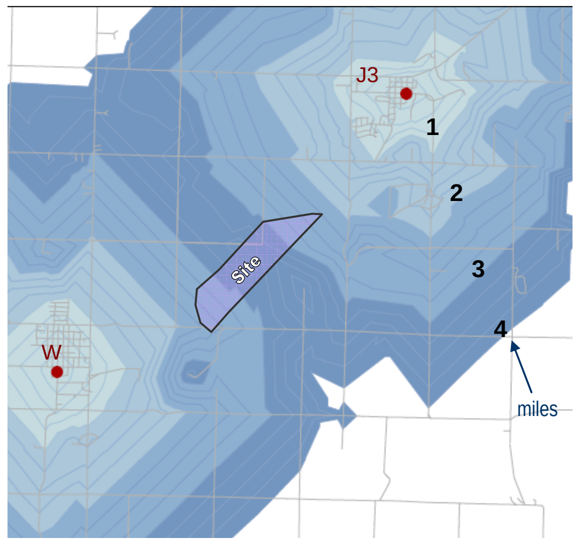
No Action

In the No Action Scenario, emergency vehicle access routing and distances are expected to remain as outlined in Section 2.2.7 (Figure 2-15). However, two future changes would affect emergency vehicle access: the volume of train traffic is expected to increase over time and the average length of those trains is expected to increase. This would increase the potential for delay (and longer delays) when responding vehicles must cross railroad tracks.

Wellsville North Alternative

The construction of an IMF at Wellsville North would result in changes to the local roadway network, but these changes are not expected to negatively impact emergency vehicle response distances from either the Wellsville (W) or Edgerton (J3) station locations. The main changes would be increased reliability of travel times due to additional grade separations in the area. For this site, the only anticipated road closure would be along 215th Street between Evening Star Road and Edgerton Road. As the road network in this area is a grid system, there are other roads that can be used instead of this road, with little or no effect on travel distance. Figure 3-39 shows the emergency vehicle response distances for both stations with the closed portion of 215th Street eliminated. There is essentially no difference between these response distances and the No Action response distances.

Figure 3-39:
Distance from Emergency Response



With the new grade separations, both stations could serve either side of the BNSF mainline without crossing rail lines at-grade, and emergency vehicle response impacts would be considered minor.

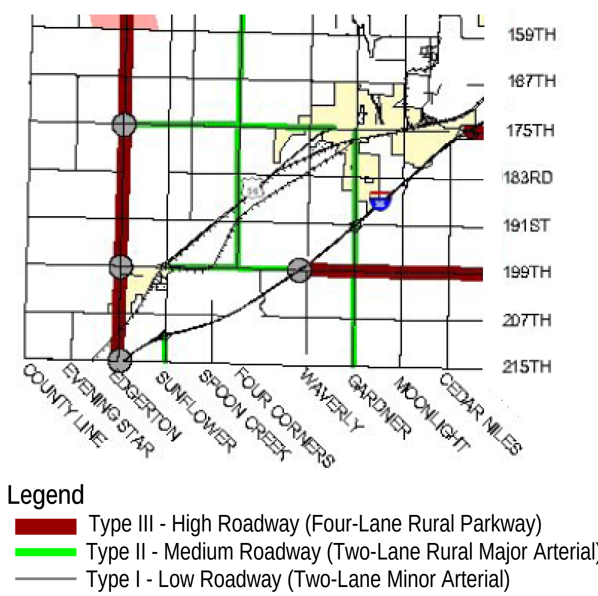
3.5.9 Circulation System

No Action

In the No Action Scenario, the local and regional connectivity in the vicinity of the Wellsville North Alternative would remain similar to what it is today, with a few exceptions. The exceptions include the following:

1. Development will continue in the area. This will include more dense development in the areas with water and sewer service.
2. Railroad traffic will continue to increase (as outlined previously), leading to increased potential for delay at mainline railroad crossings.

Figure 3-40:
Johnson County CARNP – Wellsville Area



There are no major new highways or interchanges currently planned or funded in the immediate vicinity of the Wellsville North project site that have been deemed reasonably foreseeable. However, the Johnson County CARNP shows a new grade-separated access point on I-35 at Edgerton Road (refer to Figure 3-40). This would improve regional connectivity in the long-term if implemented. The CARNP also shows upgrades to Edgerton Road (to the north) and Sunflower Road (to the south). Specifically, Edgerton Road is shown as a four-lane rural parkway (Type III – High Roadway) north of I-35. South of I-35, Sunflower Road is proposed as a two-lane rural major arterial (Type II – Medium Roadway). 207th Street and Sunflower Road north of I-35 are shown as two-lane minor arterials (Type I – Low Roadway).

Overall, few reasonably foreseeable major changes to the local circulation patterns are expected in the vicinity of the Wellsville North project site, though the existing local highways may be improved to provide enhancements to existing connections.

<u>Wellsville North Alternative</u>
With the Wellsville North Alternative, the circulation in the vicinity of the site would be changed somewhat due to the closure of 215th Street (between Evening Star Road and Edgerton Road). However, given the current (and expected future) low traffic volume on this section of roadway – the 2005 ADT was approximately 30 vehicles – this closure is not anticipated to substantially change local circulation and connectivity. It was also assumed that roadways west of the Wellsville North Alternative site (such as 215th Street west of Evening Star Road) would remain gravel and would not be available for commercial truck use.

3.5.10 Roadway Design Considerations

<u>No Action</u>
In the No Action Scenario, the highway system could be expected to continue to evolve in a manner consistent with past trends. This would include periodic roadway upgrades as needed, that meet the then current state and local roadway design standards. Some of these improvements may be initiated by public agencies and some by private developments. In the immediate vicinity of the IMF, there are few currently planned highway design improvements. As outlined under *Circulation System* above, long-term improvements are being considered for Edgerton Road including a possible new interchange on I-35.

<u>Wellsville North Alternative and Future IMF Operations</u>
With the Wellsville North Alternative, a number of the local roads would need to be upgraded. This would likely include upgrades to Evening Star Road, 207th Street, and Sunflower Road; also, 207th Street would include grade-separated crossings over the BNSF tracks. These roads would be designed to meet applicable state and local standard and, including pavement depth and type appropriate for the projected auto and truck traffic. In all Wellsville North Scenarios (2010, 2015, and 2030), the vast majority of IMF trucks are forecasted to use these roadways to travel to and from I-35. Therefore, roadway design issues related to the project would be minimal for these scenarios.

3.5.11 Construction Traffic

Construction of the Wellsville North Alternative, including related infrastructure, would occur over a period of 18 to 22 months. Major road and bridge construction would potentially be completed in the first 12 months. Construction staging areas would mainly be on site, though some off-site areas may be used related to the roadway and bridge construction. Access to all homes and properties along the affected roadways would be maintained during construction and is considered a minor impact.

Construction could affect local residents due to short-term or partial road and railroad crossing closures as well as the effects of construction traffic to and from the site. Major access to the Wellsville North site during construction would likely be the same as during normal operations.

Therefore, any traffic impacts would likely be along the same access corridor of Sunflower Road, 207th Street, and Evening Star Road. The primary expected types of traffic include construction employee traffic, equipment/supply traffic, and material hauling traffic. However, it is not currently known how much construction traffic in each category would be generated by the Wellsville North Alternative. A traffic management plan should be developed in conjunction with the local communities and counties as part of the development of construction phasing and implementation plans.

3.6 Indirect Effects – Future Wellsville North IMF Operations plus Induced Development

It is unclear what or how much new traffic-generating development would be induced if the Wellsville North Alternative were implemented. There are no current plans to develop a warehousing facility in the vicinity of the Wellsville North Alternative. However, if an IMF were sited at Wellsville North, it is likely that a certain amount of warehousing or other industrial development would be induced by the IMF operation. It is also possible that an IMF sited in the Wellsville North development area could induce commercial land use, such as convenience stores, gas stations, and restaurants; however, no information exists as to the nature and location of such development. Given this uncertainty, it is difficult to project specific future traffic flows or impacts. This applies to intersection/roadway capacity, freeway facility capacity, and also general roadway circulation and access.

The amount of induced development in the area surrounding the Wellsville North Alternative cannot be quantified. However, it is reasonable to conclude that any substantial induced development in this area could cause some of the low-capacity rural intersections and roadways in the area to need further improvements. This could include improvements to the I-35/Sunflower Road interchange and additional improvements along 207th Street.

In addition, because the induced development surrounding the Wellsville North Alternative cannot be quantified, it is not possible to quantitatively assess indirect effects in the areas of transit use or service, pedestrian/bicycle activity or facilities, at-grade rail-crossing volumes or delay, or emergency vehicle access. Even qualitative assessments would be speculative without some level of information regarding the type, size, and location of induced development.

4.0 POTENTIAL MITIGATION MEASURES

4.1 Gardner

Mitigation measures are discussed in the *Mitigation Technical Report* (HDR, 2008c).

4.2 Wellsville North

Mitigation measures are discussed in the *Mitigation Technical Report* (HDR, 2008c).

APPENDICES

Appendix A:
Methodology

Appendix A - Methodology

The traffic analysis methodology employed for this study is based on widely accepted traffic engineering approaches and procedures. The methodology was presented to Federal, state and local agency staff for their review and concurrence. One methodology presentation was given on November 30, 2007. A second presentation (highlighting the additional analysis for the Wellsville North Alternative) was given on February 8, 2008. In addition to these NEPA methodology presentations, there were many methodology meetings and discussions that preceded the current NEPA traffic analysis. These discussions took place over the course of the previous 16 months in conjunction with the *I-35 Break-In-Access Study near Gardner, KS*. During these meetings, a variety of traffic forecasting and analysis methods were presented, discussed, and agreed upon. Some of these applied directly to the NEPA analysis work that followed.

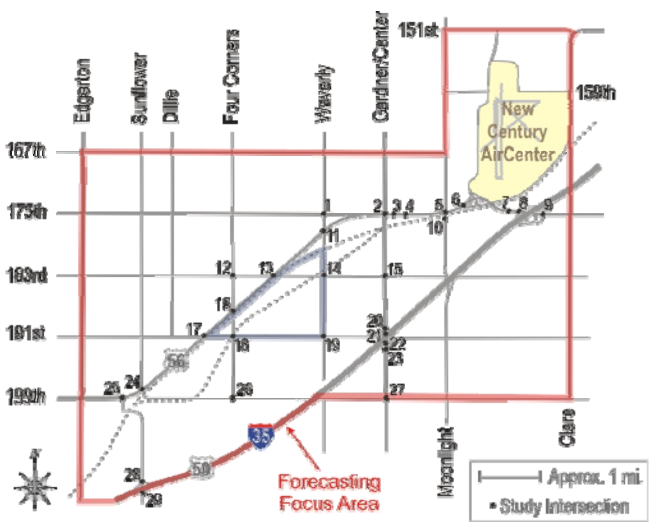
This appendix provides a summary of key study methodologies in six main topical areas:

1. Study Area and Study Facility Identification
2. No Action Traffic Forecasts
3. Gardner Proposed Action and Future Gardner IMF Operations Traffic Forecasts
4. Gardner IMF Operations + Induced Development Traffic Forecasts
5. Wellsville North Alternative Traffic Forecasts
6. Traffic Operations Analysis Methods

Study Area and Study Facility Identification

In late 2006 / early 2007 a Traffic Forecasting Focus Area was defined as part of the *I-35 Break-in-Access Study* (BIA). This Focus Area was set through a consensus process that involved the critical Federal, state, and local agencies. The Traffic Forecasting Focus Area is shown in Figure A1. It was determined that this Focus Area addressed an area more than adequate for capturing the potential NEPA traffic impacts of the Proposed Action. Therefore, this proposed Gardner traffic study area and a set of specific highway facilities within the study area were presented to the agencies and received their concurrence for inclusion in the NEPA traffic analysis methodology.

Figure A1: I-35 BIA Traffic Forecasting Focus Area

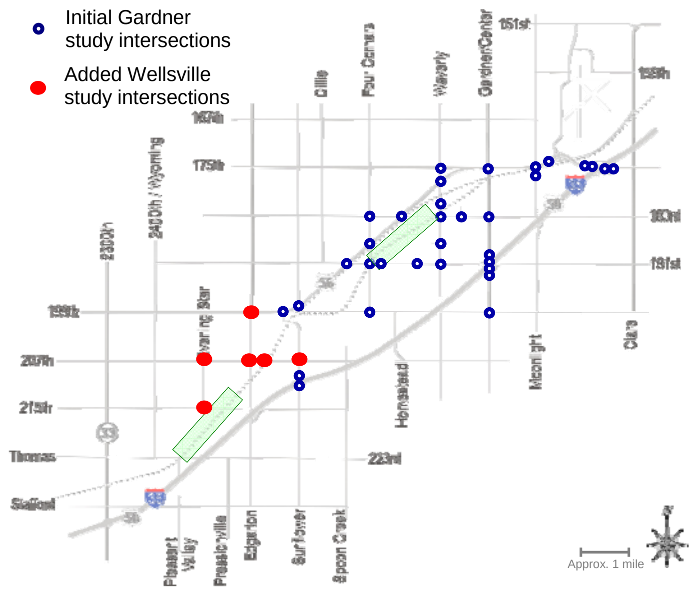


The facilities addressed in the analysis included critical intersections, freeway ramps, and freeway mainline sections in the Gardner traffic study area as displayed in the body of the report. The study intersections included major intersections along arterials and collectors that could be impacted by the proposed project (e.g. US 56, Gardner Road, and 199th Street) as well as some more remote intersections that were deemed important. The only adjustment made to the study facilities between the BIA meetings and the NEPA documentation was that the Sunflower Interchange and freeway segments to the south were not studied in the Gardner scenarios because they were found to attract an inconsequential amount of traffic from the Gardner IMF.

For the Wellsville North Alternative, the Edgerton vicinity was added to the prior Gardner traffic study area. This new area and the added intersections were shown to the resource agencies at the February 2008 methodology meeting (see Figure A2). To determine which of the intersections included in the Gardner Area should be included in the Wellsville North analysis, a threshold of 10 peak-hour project trips and a two percent increase in peak hour traffic (by movement) was applied to each intersection. Intersections that did not meet this minimum threshold during at least one peak hour were not examined in detail for capacity purposes. Again, the actual study intersections, ramps, and freeway sections are presented in the body of the report.

No Action Forecasts

Figure A2: Wellsville Alternative Site Vicinity and Study Intersections



Existing Volumes

Existing traffic volumes were developed based on recent daily and peak-period count data as outlined in the body of the report. The count data was smoothed to provide balance between various study intersections and freeway facilities. Truck volumes were also estimated based on the available truck counts in the Gardner and Wellsville North study areas. These existing (2008) traffic volumes provided the basis for the 2010 and 2015 No Action forecasts.

2010 / 2015 No Action Forecasts (Both Study Areas)

The 2010 and 2015 No Action traffic forecasts for both the Gardner and Wellsville North study areas were developed using growth rates and applying them to the baseline 2008 volumes. Traffic growth rates were originally investigated during the I-35 BIA study process. Further investigation of historical KDOT count data during the NEPA traffic analysis work confirmed the use of 2.8 percent as the near-term compounding growth rate for local, collector, and arterial roadways in both the Gardner and Wellsville North areas. A near-term rate of approximately 3.2 percent was employed for I-35. These growth rates were applied to all study intersections and highway links. Traffic volumes were balanced between various intersection and freeway facilities taking into account access and development intensity considerations. Additional adjustments were made when dictated by a specific condition such as the re-alignment of 191st Street to connect to Gardner Road at 188th Street or a specifically known approved development such as the Sunflower Ridge Subdivision in Edgerton.

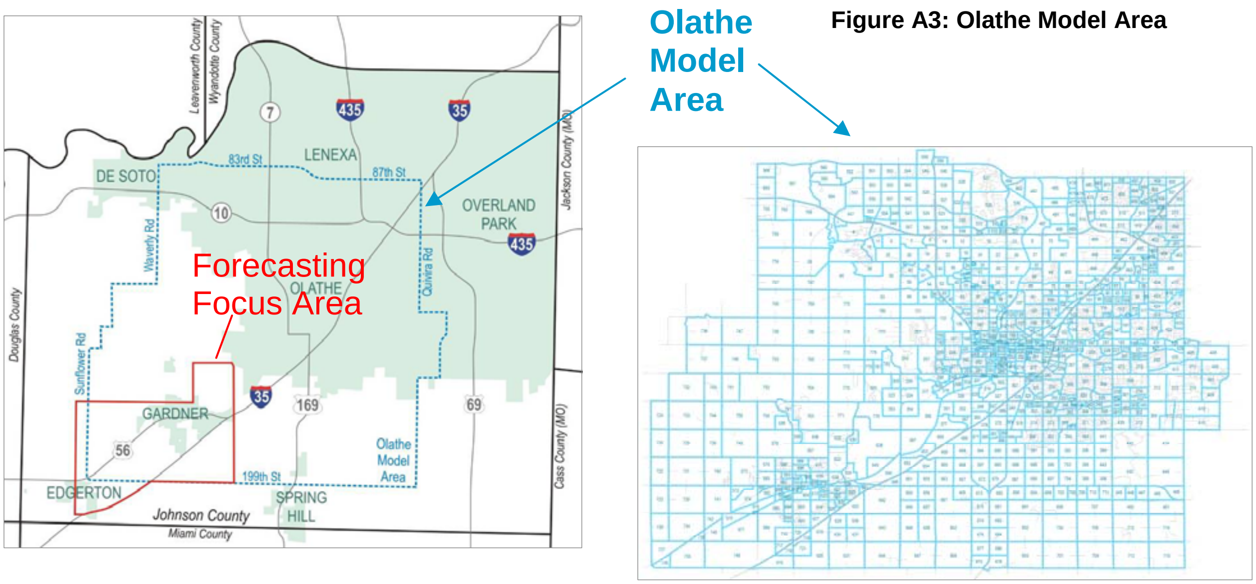
2030 No Action Forecasts (Gardner Area Only)

To develop the long-term 2030 traffic forecasts for the Gardner study area, a very different approach was employed. For these forecasts, the City of Olathe's computerized travel demand forecasting model was selected as the most appropriate platform. The original model provided by the City of Olathe for this analysis covered the majority of the study area and included land-use forecasts for 2010, 2015, and 2050. The use of this model for projecting traffic in the Gardner area was initially presented to the appropriate Federal, state, and local agencies during the I-35 BIA study process. They agreed that it was the best available method for developing long range forecasts for this area. Therefore, in partnership with the agencies, a set of 2030 land-use and transportation network assumptions were developed for the Traffic Forecasting Focus Area. These assumptions formed the basis of the 2030 No Action model runs for the current NEPA analysis. A summary discussion of the model, key assumptions, and other related topics is presented in this document. Additional details especially regarding No Action land-uses and the treatment of model external stations are included in the I-35 BIA report and appendices.

Forecasting Model

The Olathe Travel Demand Model (OTM) uses the TransCAD modeling software to forecast daily and p.m. peak hour forecasts for a typical weekday. The OTM covers an area about 14 miles long (north-south) and 15 miles wide (east-west). The approximate model limits are 87th Street/83rd Street to the north, Quivira Road to the east, 199th Street to the south, and Sunflower Road to the west. The model boundary is illustrated in Figure A3. The OTM divides the region into 782 internal Traffic Analysis Zones (TAZs), which allow existing and future land-use/socioeconomic information to be grouped into reasonably sized areas. These TAZs are joined to the transportation network by links known as centroid connectors, and the OTM - through an iterative process - generates, distributes, and assigns traffic to the transportation network. In addition to the 782 internal TAZs, the OTM includes 72 external zones that represent traffic heading in and out of the model (such as I-35 south of 191st Street).

Figure A3: Olathe Model Area



Land-Use Forecasts

The Traffic Study Corridor is at the southwestern edge of the Olathe model; in fact, the Sunflower Interchange is outside the OTM. Much of the area within and near the Traffic Study Corridor is in a state of flux regarding future land-use and transportation planning; therefore, to prepare the OTM for the needed analysis, the 2030 land-use and network assumptions were reviewed and refined. Refining these assumptions involved extensive input from multiple agencies (Agencies), including the Kansas Department of Transportation (KDOT), the Federal Highway Administration (FHWA), the City of Gardner, the City of Edgerton, the City of Olathe, Johnson County, Miami County, and the Mid-America Regional Council (MARC). Through an extensive, collaborative process, these agencies reached consensus regarding the 2030 land-use and network assumptions to be included in the OTM.

The original Olathe model included four horizon years: 2004 (existing), 2010, 2015, and 2050. Since 2030 was identified by the Agencies as the desirable long-term year for traffic forecasting and impact analysis, a new set of land-use assumptions had to be developed for this model horizon year. The process for creating the approved 2030 land-use inputs included (1) Linear interpolation between the OTM's 2015 and 2050 land-use scenarios, (2) Specific inputs by the City of Gardner related to future growth within and near the City, and (3) extensive review and input from the remaining Agencies, especially Johnson County and the City of Edgerton. The process also included manipulation of the OTM's external link volumes to represent relevant expected growth beyond the OTM edges (such as redevelopment of the Sunflower Army Ammunition Plant site).

In addition to the agency coordination described above, several comprehensive planning, land use, and zoning documents were obtained and reviewed to identify future land-use and transportation plans/assumptions within or near the Traffic Study Corridor that might affect the 2030 No Action Scenario. The following documents and studies were considered:

- Miami County - *Comprehensive Plan*, September 2004
- Johnson County – *Comprehensive Arterial Road Network Plan (CARNP)*, January 1998
- Johnson County – *The Rural Comprehensive Plan*, June 2004
- Johnson County - *Sunflower Army Ammunition Plan Conceptual Land Use Plan*, June 1998
- Johnson County Planning Commission - *New Century AirCenter Comprehensive Compatibility Plan*, February 1996
- Johnson County & Tetra Tech EM, Inc. - *Sunflower Army Ammunition Plant Supplemental Environmental Assessment,* January 2004
- City of Olathe - *2005 Transportation Study*
- Gould Evans Goodman Associates - *Lone Elm Vicinity Plan* and Draft Update, June 2000 and February 2007
- City of Edgerton - *Comprehensive Land Use Plan*, 2000

- City of Gardner - *Comprehensive Plan*, 2003
- KDOT - *K-10 Transportation Study*, May 2005
- KDOT & Johnson County – *K-10 Corridor Study Update*, January 2004
- KDOT (HNTB & HDR)- *K-7 Corridor Management Plan*, February 2006
- City of Olathe (HNTB) - *I-35 & Lone Elm Road Interchange Environmental Assessment*
- MARC - *South Metro Connector Study* (ongoing)
- KDOT (HDR) - *I-35 in Gardner, KS Break In Access Study*

The finalized land-use scenario included adjustments to account for known major developments and plans in the area including: Sunflower Army Ammunition Plant, Lone Elm Plan, development at New Century AirCenter, and other expected growth in Gardner. Further details regarding the approved land uses in the 2030 model are available in Appendix A of the I-35 BIA which includes the *Land-Use and Traffic Forecasting Assumptions Memorandum* (HDR, 2/2/07) and the September 2007 memo addendum.

Model Roadway Network

The model network was also updated to an anticipated 2030 condition. The process for creating the 2030 No Action model network was similar to the land-use update process, involving starting from the 2050 network as a base and working with the Agencies to gain consensus regarding appropriate additional modifications. Based on working with the Agencies, a number of additional improvements were included in the No Action Scenario. The major additional assumed improvements are illustrated in Figure A4 and key assumptions are listed below. (Some of the improvements listed below only affect the 2030 No Action capacity analysis and not the modeling, but they are included for context and reference.)

- *I-35 mainline* – It is assumed that I-35 will be widened to six lanes from 151st Street to a new interchange in the vicinity of 199th Street and Waverly Road.

- *I-35/Gardner Road interchange and vicinity* – The assumptions at this interchange include signalization of both ramp terminals, and the addition of right-turn lanes at the southbound ramp intersection (westbound and southbound approaches). It is further assumed that both 191st Street intersections with Gardner Road will be moved several hundred additional feet away from the interchange to provide adequate separation to facilitate traffic flow. On the north side, this would tie into the current 188th Street alignment west of Gardner Road (including intersection signalization).

- *I-35 / 199th Street & Waverly Rd. Interchange Constructed* – Based on input from KDOT, by 2030 a new interchange was assumed to be constructed on I-35. For modeling purposes, it was assumed that the interchange was consistent with the CARNP and was located near 199th Street and Waverly Road. The interchange concept used in the analysis was a simple diamond with ramps to 199th Street. Waverly Road was offset and was discontinuous to the north and south.

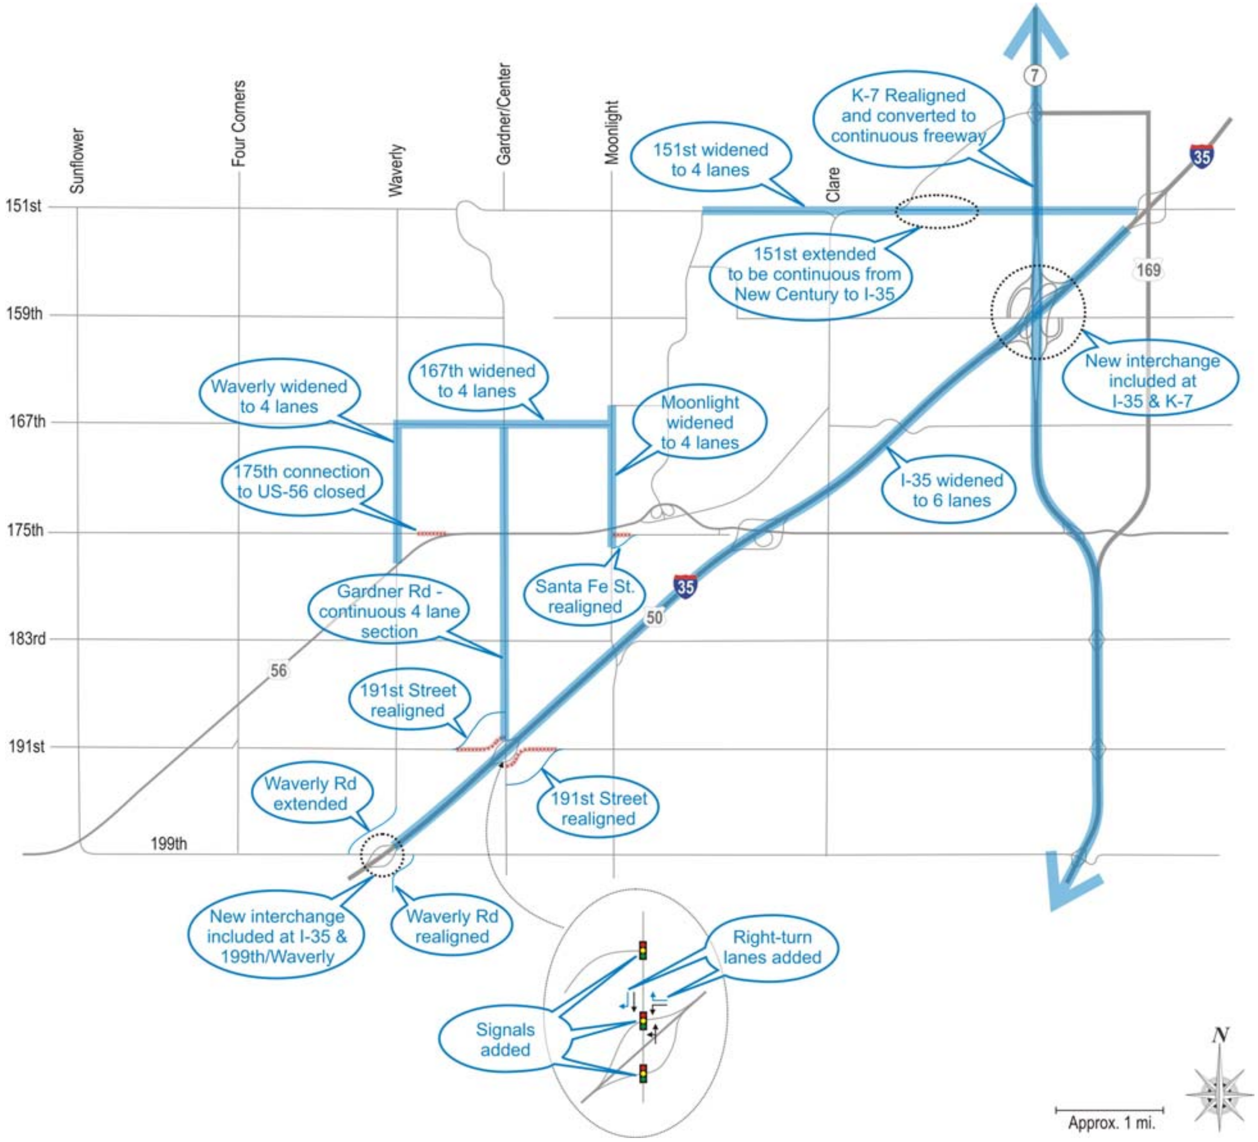
- *K-7* – In keeping with the recommendations of the *K-7 Corridor Management Plan,* the 2030 No Action scenario assumes that K-7 will be converted to a continuous freeway from Spring Hill north through Olathe. This includes a new freeway-to-freeway interchange with I-35 in Olathe. K-7 is not near Gardner, but it is in the OTM and heavily influences regional traffic volume distributions.

- *151st Street* – It is assumed in the 2030 model that 151st Street will be a four lane roadway from New Century Road east to I-35, continuing over the railroad tracks east of Old US 56 where it currently is discontinuous.

- *167th Street* – It is assumed that 167th Street will be widened from two to four lanes between Waverly Road and Moonlight Road.

- *175th Street* – The “triangle” created by 175th Street, US 56, and Waverly Road presents challenges for traffic operations and it will continue to do so as traffic volumes increase. The 2030 No Action scenario assumes that the 175th Street connection to US 56 will be closed so that motorists traveling between 175th Street and US 56 will need to use Waverly Road.

Figure A4: Anticipated Major Transportation Network Improvements in the Gardner area by 2030



- *Gardner Road* – Much of Gardner Road between US 56 and I-35 already consists of a four-lane cross-section, but there are several areas with only two lanes. The 2030 No Action scenario assumes a complete four-lane facility for this entire segment, including the widening of the bridge over the BNSF tracks.

- *Waverly Road* – It is assumed that Waverly Road will be widened to four lanes between US 56 and 167th Street.

- *Moonlight Road* - It is assumed that Moonlight Road will be widened to four lanes between Santa Fe Street and 167th Street, and that the Moonlight Road/Santa Fe Street intersection will be relocated approximately 600 feet south to provide better separation from the BNSF tracks and US 56.

- *Local Streets* – Some of the existing roads between US 56 and I-35 are currently low-volume gravel roadways, including Waverly Road, 191st Street, and 183rd Street. Johnson County's CARNP shows these roads as future paved facilities. The 2030 No Action model increases the capacities of these roadways to reflect the CARNP recommendations. Speeds on some of the local roads were also adjusted to better reflect expected 2030 conditions.

- *Intersection Upgrades* - Many of the study intersections, especially those along US 56, are assumed to be upgraded under the No Action scenario to attempt to provide sufficient capacity for the 2030 No Action volumes.

The OTM includes many other assumptions regarding future improvements for the entire area covered by the model. These underlying model assumptions were not changed as part of this project.

2030 Volumes
Using the above land-use and network assumptions the model was used to develop 2030 daily and p.m. peak hour traffic volumes in the Gardner area. The resulting "raw" model output was then post-processed to develop final volumes. This included calculating, and in many cases applying, the difference between the calibrated base model output and comparison traffic counts (both for links and intersections).[1] This helped ensure that localized traffic patterns were taken into account and that under- or over-representation of volumes were corrected. Existing truck traffic was also examined to develop balanced estimates of future truck volumes. (The OTM does not forecast trucks separately from non-trucks.) It was assumed that background truck growth was similar to the overall traffic growth on a daily basis, but that it grew at approximately 75 percent of that rate during the a.m. and p.m. peak hours. The final volumes were then reported in figures and used in the capacity analysis.

Because the Olathe model does not have an a.m. peak hour component, a process was developed to produce a.m. forecasts. This involved first comparing the a.m. and p.m. peak hour data in the Gardner area. This comparison revealed that the two data sets have definite reverse flow characteristics. Many key movements are heavy in one direction in the a.m. peak hour and in the reverse direction in the p.m. peak hour. It also revealed that the a.m. peak hour volumes were approximately 93 percent of the p.m. peak hour volumes overall. Therefore, the p.m. peak hour model trip matrix (origins and destinations) was transposed (flipped) and factored (by approximately 0.93) to develop an estimated a.m. trip matrix. This a.m. trip matrix was then assigned to the 2030 network to provide 2030 a.m. peak hour "raw" model output. Again, this data was adjusted based on a comparison of a base year a.m. model run (developed using the same process) and comparison traffic counts. Balanced truck volumes were also estimated.

The final volumes were determined to be representative of the anticipated 2030 No Action peak hour and daily traffic flows, based on the approved land use and network assumptions.

2030 No Action Forecasts (Wellsville North Area Only)
The 2030 No Action forecasts for links and intersections in the immediate Wellsville North area were developed in a manner more consistent with the 2010 and 2015 forecasts. This was necessary because the OTM boundary is Sunflower Road in the west and 199th Street in the south. Therefore, growth rates were used outside the model area to project a baseline traffic increase to 2030. Then additional adjustments were made to account for expected growth not included in these growth factors. This included traffic growth due to the Sunflower Army Ammunition Plant, the Sunflower Ridge Subdivision, and new residential growth in Miami County. Land-use planning documents and plans were again consulted in developing these No Action forecasts. The resulting volumes were balanced with the 2030 No Action volumes resulting from the model output for the Gardner area. Again, the final balanced volumes were presented in figures and used in the capacity analysis.

Gardner Proposed Action and Future Gardner IMF Operations Traffic Forecasts

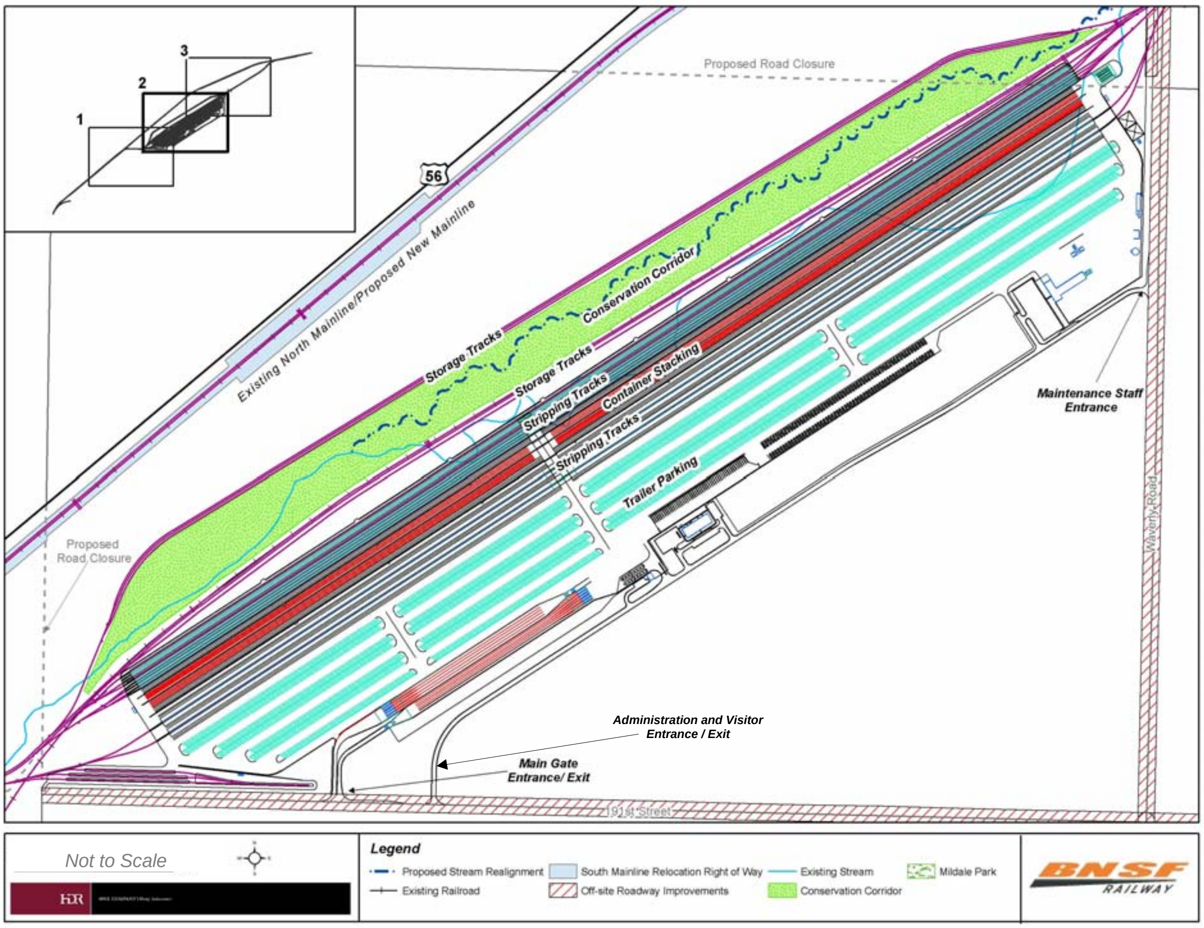
Proposed Action
The Proposed Action is discussed in detail in Chapters 1 and 2 of the Draft Environmental Report. For traffic forecasting purposes the main elements of the Proposed Action include:

- Construction of a highway-rail Intermodal Facility inside the area bounded by 191st Street, US 56, and Waverly Road as shown in Figure A5;
- Closure of 183rd Street between US 56 and Waverly Road (including two at-grade rail crossings);
- Closure of Four Corners Road between US 56 and 191st Street (including two at-grade rail crossings);

[1] For the few Gardner area intersections located outside of the model (in Edgerton) the methods described for the Wellsville North area analysis were used and the volumes were balanced to the nearest model intersection results.

- Closure of 191st Street between US 56 and Four Corners Road (including an existing at-grade rail crossing);
- Discontinued use of the existing at-grade rail crossing on 199th Street a little over half a mile west of Four Corners Road.
- Road improvements on 191st Street from Four Corners to Gardner Road (paved two-lanes and sidewalk on one side);
- Road Improvements on Waverly Road from 191st Street to US 56 (paved two-lanes);
- Grade separation of Waverly Road and the intermodal lead tracks, and
- Realignment of the southern BNSF mainline track to follow the northern track alignment between Gardner and Edgerton.

Figure A5: Proposed Action Site Plan



Key aspects of site operations and access that affect the traffic analysis include:

Truck Access: Inbound and outbound trucks using the Gardner IMF would primarily enter and exit via a common access point on 191st Street a little over a mile west of Waverly Road and about 2,000 feet east of the current intersection of 191st Street and Four Corners Road. Operations would be 24 hours a day. Incoming trucks would initially pass through an automated gate with an average processing time of 3 minutes. Once a truck has passed through the gate, it would be subject to additional internal processing. Multiple entry gates and on-site queueing storage would be provided to streamline processing and prevent queueing back onto the local street system.

Employee Access: Employee access to the intermodal site would be separate from the truck access for security and operational reasons. The main employee entrance would be on Waverly Road, approximately 1,500 feet south of 183rd Street. The visitor and administration entrance would be on 191st Street a short distance east of the truck entrance. All employee parking would be accommodated on site.

Train Volumes: BNSF anticipates that initially (in 2010) approximately six trains per day would access the Gardner IMF. By 2030, it is projected that this would increase to an average of approximately 13 trains per day.

Train Speeds: Average train speed data was provided by BNSF. Construction of the Gardner IMF is not expected to substantially affect the average mainline train speeds through the area. However, trains entering and departing the Gardner IMF may have slower speeds depending on location and direction.

Train Lengths: BNSF provided average train length data for both mainline trains and trains entering and departing the Gardner IMF. Average train lengths are forecasted to increase over time. For example, in the scenarios with the IMF, average mainline train lengths are expected to increase from 6,500 feet in 2010 to 7,400 feet in 2030, while the intermodal trains entering and departing the IMF are expected to increase from 6,850 feet in 2010 to 7,700 feet in 2030.

Gardner IMF Trip Generation

Trip generation represents the amount of traffic generated by a given project or site. For the Gardner IMF, two main variables were examined to calculate the trips generated by the project: employees and lifts. A lift is defined as the movement of a container either onto or off of a train. Table A1 presents the key variables and summarizes the daily and peak-hour trip generation rates and totals used for the proposed Gardner IMF for 2010, 2015, and 2030. The trip generation results are separated by trucks, bobtails, and non-trucks. Bobtails are trucks that are not pulling a trailer or chassis (i.e. cab only). They are separated out because they have different traffic operating characteristics than trucks with trailers.

The Gardner IMF truck trip generation is based on data derived from BNSF's existing Argentine Intermodal Facility in Kansas City, Kansas. It is anticipated that the intermodal component of the Argentine facility will be replaced by the activity in Gardner; therefore, the Argentine facility is considered to be a suitable model for the trip generation characteristics of the proposed facility. There are other intermodal facilities in the U.S. that could be comparable, but given their locations and the types of markets they serve (which differ from the market served by Kansas City intermodal traffic), they were not considered to be as representative as the Argentine facility.

Based on correlations between the reported lifts and truck trips at the existing Argentine Yard, factors were developed to convert annual lifts to daily and peak-hour truck volumes for the proposed Gardner IMF. To develop these factors, three months of in-out gate data was considered. During this three-month period, 98,809 trucks with trailers were logged either entering or leaving the yard. Bobtails use a separate gate and are not logged. A matching analysis was conducted on the reported gate data and it was determined that approximately 28 percent of these in and out truck trips matched during a rolling one hour period as illustrated in Table A2.[2] The remaining trips (72 percent) were therefore assumed to have bobtails serving the other (unreported) end of the trip. (Source: BNSF and Environ Consulting, 2007.) This resulted in 169,486 one-way truck trips (trucks and bobtails) for the three-month period or an estimated 677,944 one-way trips for the year. Of these total one-way trips it was assumed that 59.3 percent were truck-trailer trips (loaded, unloaded, and bare chassis) and 41.7 percent were bobtails.

Table A2: Three Months of Logged Matches at Argentine Yard Gate

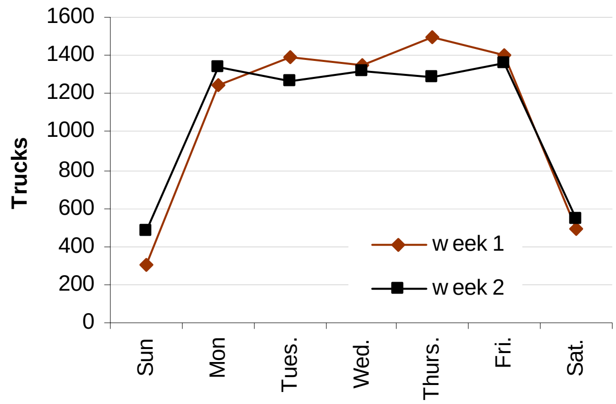
	Trucks	Percent
Logged In-Out Match (Counted Twice)	28,132	28%
Logged Out Only (Bobtail In)	35,505	36%
Logged In Only (Bobtail Out)	35,172	36%
Total for 3 months	98,809	100%

This estimated number of trips was subsequently compared to the actual number of lifts for the year, which was reported as 371,539 lifts (BNSF and Environ Consulting, 2007). This resulted in 1.064 truck trips per lift (empty, loaded, bare chassis) and 0.715 bobtail trips per lift. These were therefore, the generalized average rates (per lift) over the course of a year. The traffic analysis, however, evaluates traffic flows on a weekday and in particular it examines the flows during the morning and afternoon peak hours (when traffic on the roadways peaks due to area commuting patterns).

[2] The one hour time period was recommended by Environ staff because the shorter time frame available (30 minutes) could miss too many matches and the next longer time frame available (four hours) could introduce erroneous or multiple matches (i.e. observing the same truck three times in a time period).

Therefore, two weeks of recorded truck data was analyzed to develop a weekday factor. A summary of this data is presented in Figure A6. This analysis resulted in a weekday factor of 1.231 (ratio of the 5-day average to the 7-day average). A prior examination of monthly data had concluded that average daily lifts were fairly consistent over the year for which monthly data was available (*Traffic Study of the Proposed Logistics Park in Johnson County, KS*, HDR, 2006).

Figure A6: Recorded Trucks by Day of Week



The above trip rate information combined with the weekday factor was used to calculate an <u>average daily trip rate per million annual lifts</u> according to the following equation:

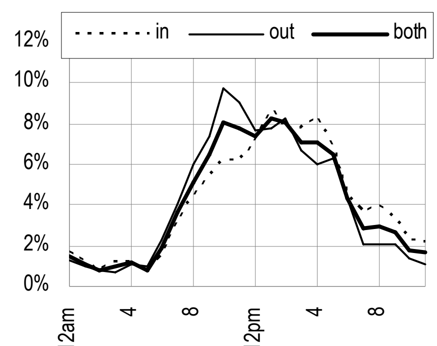
Average Daily Trip Rate Per Million Annual Lifts = (trips/lift) x 1,000,000 lifts/yr x weekday factor / 365 days/yr

Daily Truck Trips Per Million Annual Lifts = 1.064 trips/lift x 1,000,000 lifts/yr x 1.231 / 365 days/yr
~ 3588 daily truck trips per million annual lifts

Daily Bobtail Trips Per Million Annual Lifts = 0.761 trips/lift x 1,000,000 lifts/yr x 1.231 / 365 days/yr
~ 2566 daily bobtail trips per million annual lifts

As indicated in Table A1, the above trip rates result in 2,554 total truck trips (trailers and bobtails) for the opening day scenario with 0.415 million annual lifts. These average daily numbers were then adjusted to provide a.m. and p.m. peak hour trip rates through the use of hourly factors. The two weeks of daily truck count data was again examined to estimate peak period trips as a percent of daily trips and to estimate in-out flows. Data for one of the weeks is shown for reference in Figure A7. Based on this analysis the following values were used in the study: 5.5 percent of daily for the a.m. peak hour (40:60 in:out split) and 6.9 percent of daily for the p.m. peak hour (56:44 in:out split). The resulting trip rates are shown in Table A1.

Figure A7: Hourly Truck Percentages on a Weekday



Non-truck (primarily employee) traffic associated with the IMF was estimated based on employment and shift change data provided for the IMF. According to current plans, IMF ramp operation employees would comprise about 80 percent of the workforce and would have two shift changes per day (12 hour shifts). The remaining employees would have three shift changes per day (8 hour shifts). On a daily basis, a trip rate of 2.4 trips per employee was assumed to account for visitor, delivery, and other mid-day traffic. It is assumed that this rate also accounts for any carpooling and worker absences. Both sets of employees would change shifts at 7:00 a.m., therefore it was assumed that all of the 12 hour shift employees and two-thirds of the eight hour shift employees would arrive or depart during this hour. This resulted in an a.m. trip rate of 0.937 per employee. None of the shift changes would occur during the weekday p.m. peak hour, so the table shows minimal non-truck trip generation during that hour. Refer to the footnotes in Table A1 for additional information.

Given the above trip rate calculations, the number of trips generated by the IMF was calculated for each analysis year. These calculations were based on the lift count and employee data provided for each of those years. In 2010, the proposed IMF is expected to employ 143 employees with approximately 415,000 annual lifts. This is projected to generate 2,897 total daily trips on an average weekday with 273 and 185 trips expected during the a.m. and p.m. peak hours, respectively. In 2015, 495,000 annual lifts and 179 employees are forecasted for the facility leading to a commensurate increase in trip generation. In 2030, the Gardner IMF will have 288 employees with 870,000 lifts per year. This is projected to generate 6,045 daily trips on an average weekday with 563 trips during the a.m. peak hour and 388 trips during the p.m. peak hour.

Assumptions for each category:

Intermodal Daily Trucks - Annual lifts are converted to daily (7-day average), weekday, and peak-hour truck trips through a series of conversion factors developed based on existing operations at the BNSF Argentine intermodal facility in Kansas City, Kansas.

Intermodal Employees - On an average weekday, it is assumed that there are approximately 2.4 non-truck trips per employee. This includes two commute trips per employee plus a 20% factor for deliveries, visitors, and other mid-day trips. This number is also assumed to account for trip reductions related to carpooling and absences. Based on expected shift-change times, very few employee trips are expected during the p.m. peak hour. Therefore, it is assumed that a modest 3% of the weekday non-truck trips occur in the p.m. peak hour (or 0.072 trips per employee with 65% exiting). It is assumed however, that both ramp and non-ramp employees will have a shift change during the morning peak hour. This results in an a.m. peak hour trip rate of approximately 0.937 non-truck trips per employee. Employee traffic is divided into two general shift change categories:

- ramp operation employees (80% of workforce), with 2 shifts changing at 7 a.m. and 7 p.m.
- remaining employees (20% of workforce), with 3 shifts changing at 7 a.m., 3 p.m. and 11:00 p.m.

Induced Warehouse Development - Warehouse development in 2010 is 600,000 square feet. Warehouse development in 2015 and 2030 is 2.86 million square feet. Based on available data it is estimated that there are 0.6. employees per 1,000 square feet. Weekday, am peak hour, and pm peak hour trip rates are based on data presented in Truck Trip Generation Study, City of Fontana, California, August 2003.

<u>Proposed Action and 2015 Gardner IMF Operations Trip Distributions and Forecasts</u>
Trip distribution is the process of estimating where vehicle trips will begin and end. For the Proposed Action and the 2015 Gardner IMF Operations scenarios, the new trips generated by the IMF were distributed as shown in Figure A8. For non-truck traffic, the distribution was developed based on current traffic volumes and street classifications, local land use patterns, and the results of the 2030 Gardner IMF model runs. Truck traffic was distributed based primarily on the results of a BNSF high-volume shipper survey for shippers at the Argentine Yard, a SmartPort metro-wide inventory of distribution centers, and the truck assignment in the 2030 Gardner IMF model runs. The results of the first two of these items are illustrated in Figure A9. For more information on the distribution of the IMF truck traffic, please refer to the *I-35 Break-in-Access Study* – Appendix A (HDR, 2007)

Based on the distributions shown, the IMF traffic was assigned to the local roadways and intersections. The assignment assumed that IMF trucks/bobtails were restricted from using 183rd Street between Waverly Road and Gardner Road. Once the 2010 and 2015 IMF distribution and assignment were complete, the IMF project trips were added to the No Action traffic volumes to create the composite 2010 Proposed Action and 2015 Gardner IMF Operations volumes as illustrated in the body of the report.

Figure A8: 2010 and 2015 Gardner IMF Trip Distributions

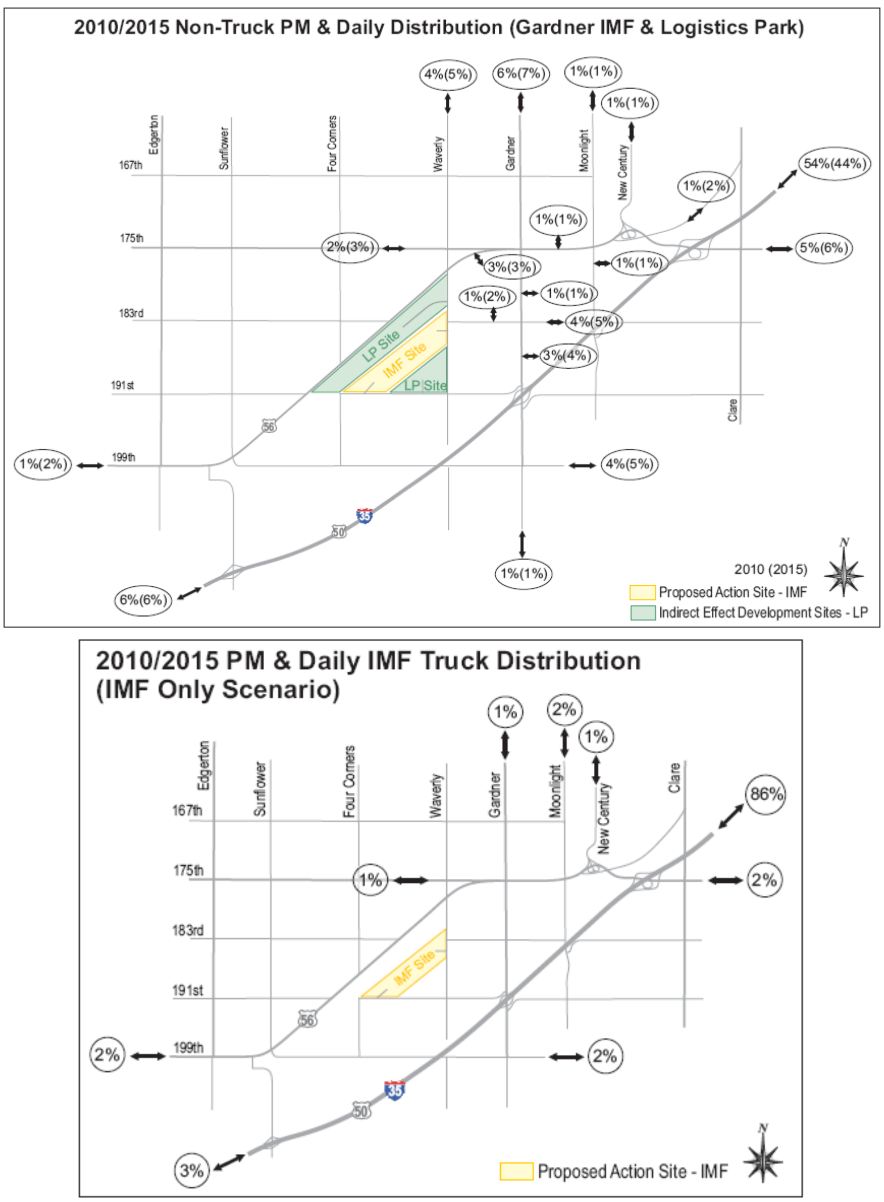

Figure A9: Sources of Data for Gardner IMF Truck Trip Distribution

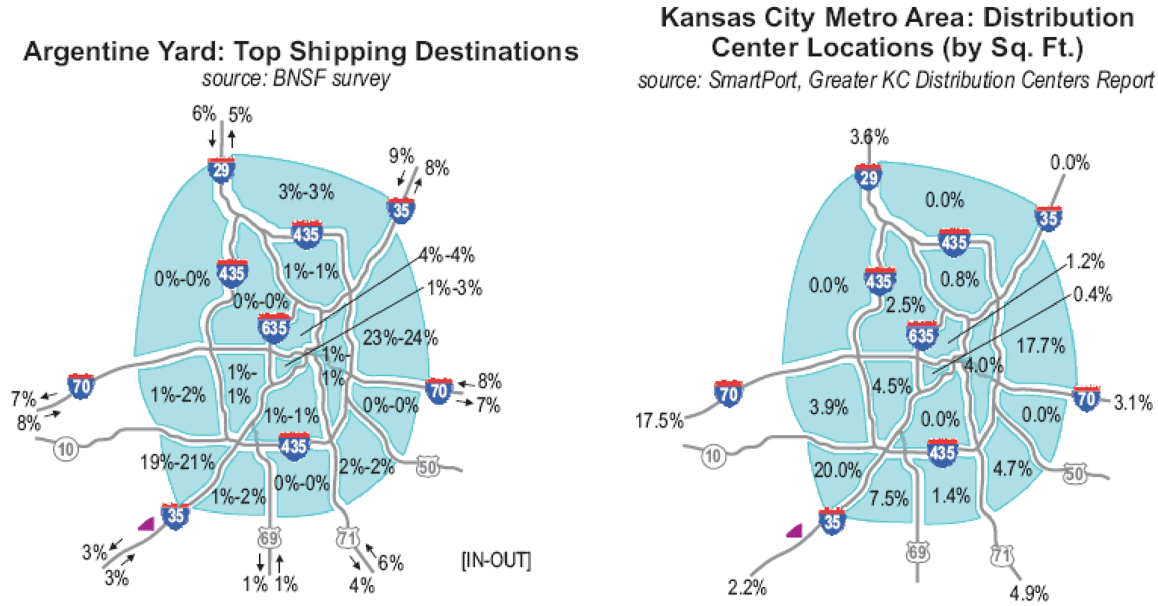


<u>2030 Gardner IMF Operations Trip Distributions and Forecasts</u>
For 2030, the trip generation shown in Table A1 was approximated in the OTM through the use of "proxy" land uses and matrix manipulation. Because the Gardner IMF land use is unique and its trip generation rates do not match any of the general rates used throughout the Olathe model, land-use totals were input into the model to "force" the desired trip generation totals. The subsequent origin-destination matrix was then further modified to approximate the trip generation total more exactly.

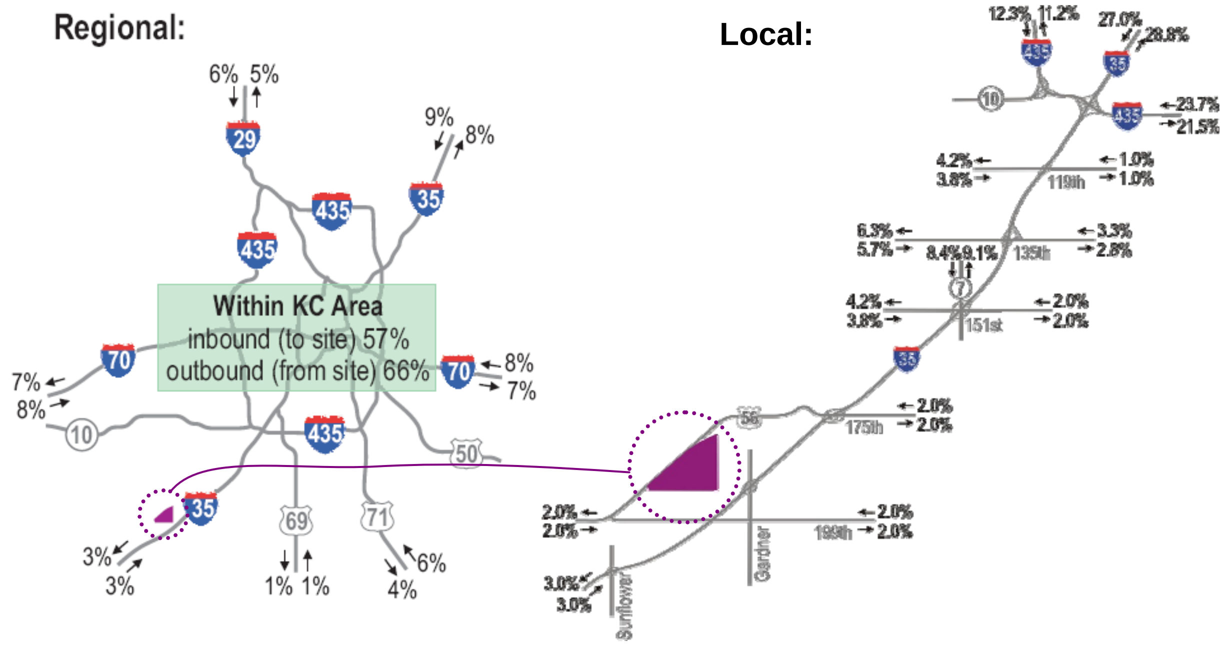
The Olathe model was used to both distribute and assign the 2030 non-truck trips generated by the IMF. The distribution was a standard "gravity" model distribution, which takes into account the number of trips produced and attracted by different "zones" and the travel time between zones to calculate the traffic flows between any two zones. Once the flows are determined, the model then assigns the traffic to the roadway network in such a way that travel time is minimized. The model takes into account the capacity limitations of the road system and will assign traffic away from congested areas if that results in faster travel times. This process was used for all of the assumed 2030 land uses in the model. The Gardner IMF truck traffic however, had to be distributed differently.

The current OTM does not include an explicit, separate truck component. Instead, trucks generated by existing and future development are implicitly included in the vehicular volume projections. (This is a standard model assumption used in many urban areas.) This means that the model does not distribute truck traffic any differently than all other traffic, and it does not take into account the effects of vehicle equivalency factors on capacity (the fact that trucks consume roadway capacity at a higher rate than non-trucks). Therefore, since the Gardner IMF will generate a higher percentage of truck traffic than would most typical non-residential uses, if the standard gravity model approach was used to distribute and assign the truck traffic, it would not appropriately assess the project impacts in the Gardner Traffic Study Area. First, it would be difficult to separate the truck traffic generated by the IMF from the auto traffic generated by the IMF. Second, because the model would distribute trucks the same way as cars, it would understate truck volumes on some roadways, while overstating them on others. The model would not assign the truck traffic in a manner consistent with its more regional and interstate origins and destinations. However, development of a separate truck component for the entire OTM would be a significant undertaking and was well outside the scope of this study.

Therefore, a third option was developed, where the 2030 truck traffic generated by the Gardner IMF was distributed deterministically based in part on the previously discussed truck origin-destination data from the Argentine Yard. These 2030 distribution assumptions were commented on and updated as part of the

I-35 BIA study process. The resulting regional 2030 IMF truck distribution is presented in Figure A10. As part of this process, the truck trip generation data was combined with the origin-destination information to create a truck traffic matrix defining the amount of truck traffic traveling between the IMF and various model zones and external stations. The model's assignment process was then used to assign that traffic to the roadway system. This allowed the model to predict which route would provide the shortest travel time. The assignment employed a 1.5 vehicle equivalency factor for trucks. It also included truck restrictions on both 183rd Street and 191st Street between Waverly Road and Gardner Road. Overall, the results of the modeling approach yielded reasonable volume forecasts for considering the 2030 volumes and impacts of the 2030 Gardner IMF Operations truck traffic.

Figure A10: 2030 Gardner IMF Truck Distribution



The network used for the 2030 Gardner IMF Operations model runs was similar to the No Action network except in the vicinity of the Proposed Action. As outlined above, the Proposed Action includes three street closures that were modeled (183rdStreet, Four Corners Road, and 191st Street). Roadway capacities and speeds in the area were set at appropriate levels and the IMF driveways were located as shown in the site plan. In addition, model assumptions were modified with respect to train crossing volumes.

As described above, the model assigned both auto and truck traffic to the roadway network based on an equilibrium process that minimizes user travel times. This final assignment provided the raw a.m., p.m., and daily model output which was then adjusted in the same manner as the No Action Scenario output. The adjusted final volumes were then presented in figures (in the body of the report) and used in the capacity analysis.

Gardner IMF Operations + Induced Development Traffic Forecasts

This section describes the traffic forecasts for the 2010, 2015, and 2030 scenarios that include the reasonably foreseeable induced warehouse development that would result from the Gardner IMF.

<u>Induced Development Assumptions</u>

Information on the potential size and location of the induced warehouse development in the vicinity of the Gardner IMF was provided by the Allen Group of Kansas. Based on this information, it was assumed that one 600,000 square foot warehouse building would be constructed in the vicinity of the IMF by 2010 and that 2.86 million square feet of warehouse space would be constructed by 2015. Based on the information provided by the Allen Group of Kansas, no further development was assumed to be reasonably foreseeable by 2030.

Induced Development Trip Generation

The auto and truck trips projected to be generated by the induced development are presented in Table A1 for 2010, 2015, and 2030. A number of approaches were explored for estimating the warehouse trip generation. This includes a thorough review of Institute of Transportation Engineer (ITE) rates, data from the 2003 City of Fontana *Truck Trip Generation Study*, and background information from other studies.

The ITE *Trip Generation* manual (7th Ed.) presents rates for warehouse and high-cube warehouse uses. However, these ITE rates did not include separate trip rates for trucks and the separation of auto and truck trips was deemed critical for this study. In fact, the ITE manual indicated that the Fontana study (actually a previous version) be consulted for truck trip rates. In addition, a detailed examination of the ITE data revealed that much of the data was from 1960 through 1990 (and nearly all of the data from east and west coast locations). Thus, it was not clear that the ITE data was representative of modern warehouse and trucking industry practices.

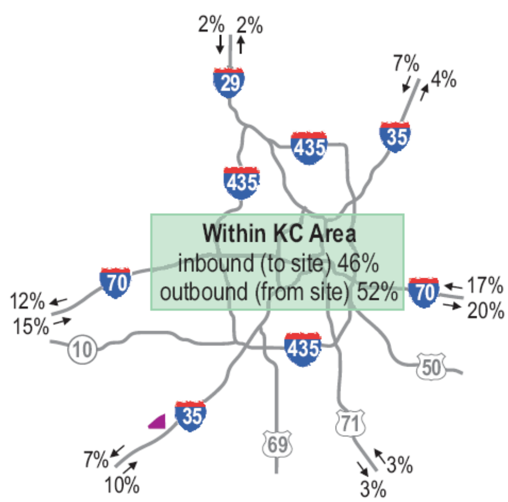
Therefore, it was decided that the Fontana Study was the best source of recent warehouse trip generation information. It also provided the necessary truck and auto trip rate information. The Fontana data was examined in considerable detail before being used for this study and appropriate daily, a.m. peak, and p.m. peak rates were employed for the analysis. The rates used are shown in Table A1 along with the resulting trip volumes.

Once these volumes were set, the truck flows between the warehouse development and the Gardner IMF were estimated for all scenarios. Based on discussions held with the agencies during the I-35 BIA Study process, it was assumed that approximately 25 percent of the warehouse traffic would travel to and from the Gardner IMF. These trips were assigned directly to and from the Gardner IMF site (with the duplicate trips eliminated).

2010 and 2015 Induced Development Distribution and Final Volumes

For 2010 and 2015, separate auto and truck trip distributions were assumed for the induced warehouse development. The non-truck distribution was the same as that employed for the Gardner IMF as shown at the top of Figure A8. It was developed based on local traffic volumes, highway classifications, local land-use, and the output from the 2030 Gardner IMF + Induced Development modeling work.

Figure A11: Regional Warehouse Trip Distribution Assumptions



Similar to the Gardner IMF truck distribution assumptions, the warehouse truck distribution was developed based on a variety of data sources. Regional truck distribution assumptions were based primarily on the Goods Movement Element of MARC's *Transportation Outlook 2030 Update and t*he U.S. Census 2002 Commodity Flow Survey (CFS) database. The regional distribution resulting from these sources is illustrated in Figure A11.

The local distribution was based on U.S. Census population data (for allocations within the region), local land-use and transportation data, and the results of the 2030 Gardner IMF + Induced Development model runs. The specific 2010 / 2015 warehouse truck distribution used for the Gardner traffic study area is illustrated in Figure A12. For more information on the development of the warehouse truck distribution refer to the I-35 BIA Appendix A.

One of the projected effects of the induced development is that it would change the distribution of Gardner IMF truck traffic. This is due mainly to the interaction between the two developments, whereby some trucks travel back and forth between the IMF and the warehouse development instead of leaving the area going to and from other destinations. The modified IMF truck distributions are shown in Figure A13. There are separate daily and peak hour distributions because, while the percentage of warehouse traffic related to the IMF was kept constant (at approximately 25 percent), the resulting percentage of IMF traffic was different for the different time periods.

Figure A12: 2010 and 2015 Induced Warehouse Development Truck Distribution

Once the various truck and non-truck trip distributions were set, the traffic was assigned to the local roadways and then added to the No Action volumes to derive final volumes for the 2010 and 2015 Gardner IMF Operations + Induced Development Scenarios. These volumes are presented in the body of the report and provided key inputs to the capacity analysis.

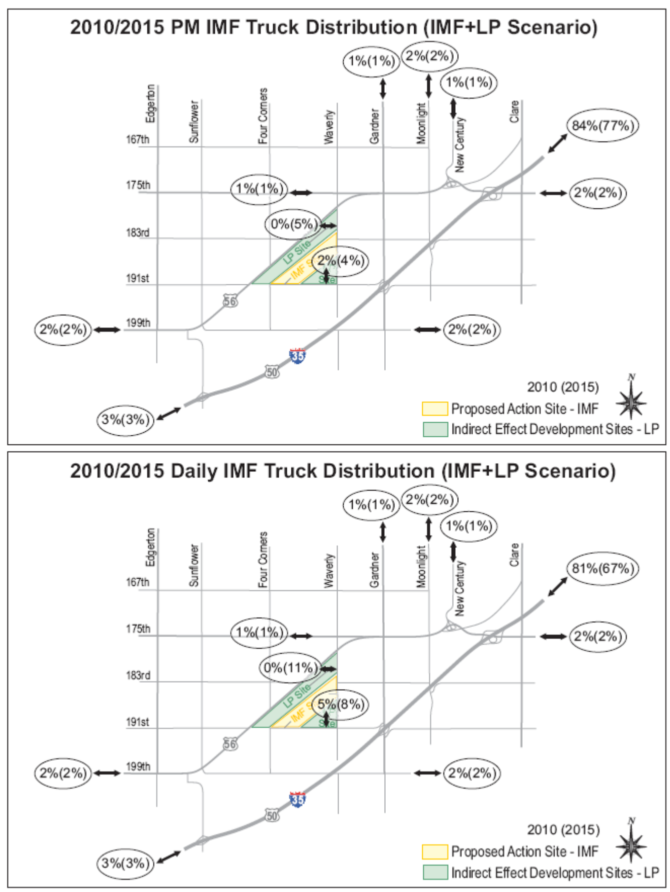
<u>2030 Induced Development Forecasts</u>

For the 2030 Gardner IMF Operations + Induced Development scenario, the OTM was again used. This time, in addition to coding the Gardner IMF trips using "proxy" land uses, the Induced Development (warehouse) trips were also coded using "proxy" land uses. Again, matrix manipulation was used to make sure the trip origins and destinations for each analysis period (a.m., p.m., and daily) were very close to what was forecasted in the trip generation step.

The model network used for this analysis was very similar to that used for the 2030 Gardner IMF Operations scenario. One change that was assumed was that the service road located north of the IMF and south of the BNSF mainline tracks would be connected by 2030 at its western end to 191st Street near Four Corners Road. This provided a second access/egress point for development along the service road in this 2030 scenario.

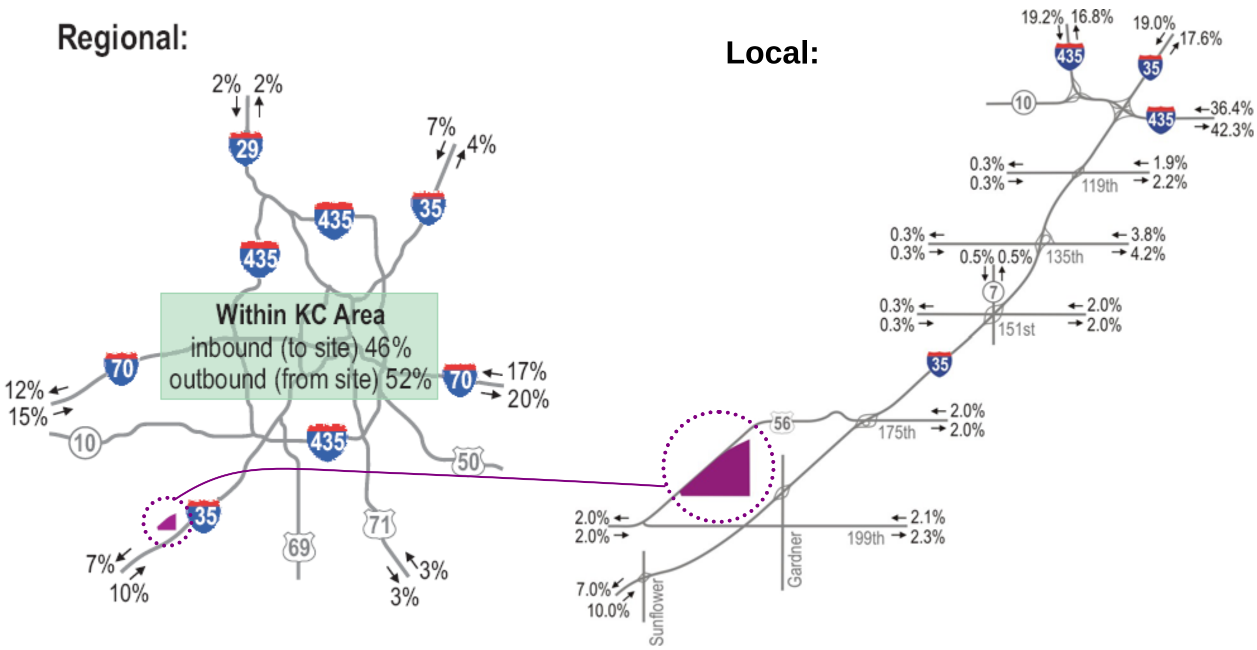
Overall, the same modeling procedure was used for this scenario as was used for the 2030 Gardner IMF Operations scenario. Autos were distributed and assigned by the model, while the commercial trucks were again assigned based on regional distribution assumptions. The regional warehouse truck traffic distribution was based on data from MARC and the US Census Bureau as discussed in the *2010 and 2015 Induced Development Distribution and Final Volumes* section. The resulting truck distribution that was used to create the truck model matrix (with origins and destinations) is shown in Figure A14. Similar to the 2030 Gardner IMF Operations truck distribution, these assumptions were reviewed and modified by

Figure A13: 2010 and 2015 Gardner IMF Truck Distribution (With Induced Development Constructed)



the Agencies as part of the I-35 BIA study process. The resulting model output was post processed as before and the final volumes were presented in the body of the report and used in the capacity analysis.

Figure A14: 2030 Induced Warehouse Development Truck Distribution



Wellsville North Alternative Traffic Forecasts

<u>Wellsville North Alternative</u>
The Wellsville North Alternative is described in Chapter 2 of the Draft Environmental Report. It includes the following major elements in relation to traffic flow on the highway transportation system:

- Improvement of Sunflower Road from I-35 to 207th Street
- Improvement of 207th Street between Sunflower Road and Evening Star Road including structures and grade separation of the mainline and intermodal lead tracks and relocation of Co-op Road.
- Improvement of Evening Star Road for a distance of approximately 5400' from 207th Street to the project site.
- Grade Separation of Edgerton Road over the mainline and intermodal lead tracks
- Grade Separation of 223rd/Thomas Road over the mainline tracks, intermodal leads and ladder tracks into the yard
- Grade separation of Main Street in Wellsville over the mainline and intermodal lead tracks.
- Closure of 215th Street between Edgerton Road and Wyoming Street

It was assumed that site access for trucks and employees is via driveways from near the Evening Star Road / 215th Street intersection.

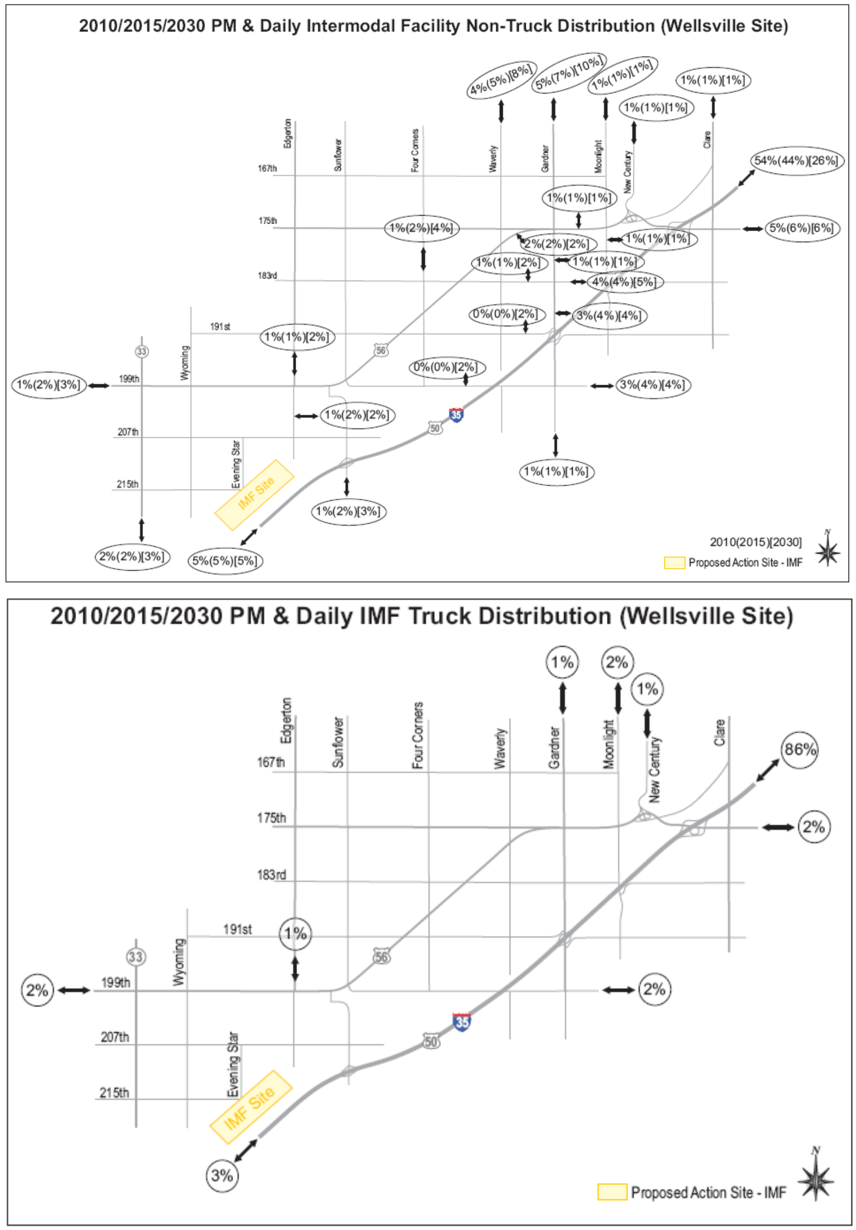
<u>Wellsville North Alternative Trip Generation</u>
The Wellsville North Alternative IMF was assumed to have the same trip generation characteristics as the Gardner IMF. Refer to Table A1 for a summary of the IMF trip generation by year.

Wellsville North Alternative Trip Distribution and Volume Forecasts

The Wellsville North Alternative is located outside of the Olathe model area. Therefore, standard manual traffic distribution and assignment methods were used for all three forecast years (2010, 2015, and 2030) and all three time periods (a.m., p.m., and daily). Given this approach, the auto trip distribution assumptions for the Wellsville North Alternative were set based on existing traffic volumes and highway classifications, local land-uses (current and projected), and the results of the 2030 Gardner IMF Operations modeling analysis. The truck distribution was based primarily on the same shipper survey / distribution center inventory information that was used for the Gardner IMF. The resulting auto and truck distributions are illustrated in Figure A15.

The Wellsville North IMF traffic was deterministically assigned to the local roadway system. These assigned volumes were then added to the No Action volumes to yield the Wellsville North Alternative scenario volumes. These volumes were presented in the body of the report and were used for the Wellsville North Alternative capacity analysis.

Figure A15: Wellsville North Alternative IMF Trip Distribution



Traffic Operations Analysis Methods

The traffic analysis approach was consistent with standard traffic engineering practice and was based upon several methodology sources, including:

- *Highway Capacity Manual (HCM)* – Transportation Research Board (TRB), 2000
- *Manual of Uniform Traffic Control Devices (MUTCD)* – FHWA, 2003 Edition
- *A Policy on Geometric Design of Highways and Streets* - AASHTO, 2004

The operational analysis focused on the critical weekday a.m. and p.m. peak hours, though daily traffic volume data was presented as well. For all scenarios, a peak-period capacity analysis was prepared based on the methods presented in the *Highway Capacity Manual*. The HCM provides standard traffic operational analysis methods for intersections, freeways, and ramps (merge and diverge).

Level of Service

Level of Service (LOS) is the fundamental HCM parameter describing operational conditions within a traffic stream. LOS is an A-through-F letter ranking scale with LOS A indicating free-flow, low density, or nearly negligible delay conditions and LOS F indicating facility breakdown with low speeds, high densities, and high delay. For intersections, LOS is based on the average control delay per entering vehicle measured in seconds. Control delay includes not only stops at intersections, but also slower speeds as vehicles advance in queue or decelerate upstream of an intersection. For signalized and all-way stop-controlled intersections, individual approach delays as well as an overall average delay are calculated for each intersection. For one and two-way stop-controlled intersections, the delay is only reported for non-free movements. For freeway elements (including both segments and ramps), LOS is based on density, defined as the number of vehicles per mile per lane. Table A3 shows the LOS criteria used in this study. The HCM methods were implemented using the Highway Capacity Software (HCS+) for freeways and ramps, and the Synchro Version 7 software for intersections.

Table A3: Level of Service

Level of Service	Intersections			Freeways		
	Description	Control Delay (sec/veh)		Description	Maximum Density (veh/mi/ln)	
		Signalized	Unsignalized		Mainline	Ramps
A	Most vehicles do not stop	≤ 10	≤ 10	Free flow	11	10
B	Some vehicles stop	> 10 and ≤ 20	> 10 and ≤ 15	Slight restriction to free flow	18	20
C	Significant number of stops	> 20 and ≤ 35	> 15 and ≤ 25	Restrictions to free flow	26	28
D	Many stop, individual cycle failure	> 35 and ≤ 55	> 25 and ≤ 35	Noticeable restriction, declining speeds	35	35
E	Frequent individual cycle failure, at capacity	> 55 and ≤ 80	> 25 and ≤ 50	No gaps in traffic, volatile speeds	45	>35
F	Arrival rate exceeds capacity	> 80	Demand > capacity	Breakdown, large queues, recurring congestion	>45	demand > capacity

Source: Highway Capacity Manual (HCM), 2000

LOS Thresholds

Based on AASHTO's *A Policy on Geometric Design of Highways and Streets,* operations within a rural area should target a Level of Service (LOS) C or better for future conditions; for urban areas, the guidelines suggest a target LOS of D or better. For this study, since many of the critical intersections are either in developed areas (e.g. Downtown Gardner), rapidly developing areas (e.g. I-35 / US 56 interchange area) or in areas that are expected to develop over the 22-year planning horizon (e.g. I-35 / Gardner Road Interchange area), a minimum standard of LOS D was chosen, along with LOS C as a desirable goal.

Highway-Rail At-Grade Crossing Analysis

The central element of the Proposed Action is the construction of a rail-truck intermodal facility. Given that this facility would affect both train speeds and local train routing, it was determined that an analysis of the highway-rail at-grade crossings was important. A review of the available analysis tools for examining at-grade crossings gave mixed results. In fact, one source stated, “Numerous methods to estimate delay at gated crossings have been tested, but there is no universally accepted procedure.” Therefore, in order to properly investigate the change in critical operating characteristics for the various study scenarios, a set of detailed spreadsheets were developed. The spreadsheets included a range of operational data such as train volumes, train speeds, train lengths, and highway volumes (train operational data was supplied by BNSF). The data allowed for a calculation of approximate blocked time (the time the roadway was blocked to highway traffic).Then using a set of equations related to queuing theory, estimates were developed for other key parameters such as average highway vehicle delay and how many highway vehicles were delayed at the crossing.

Key Assumptions

1. Factors were used to convert average daily trains (7-day average) to average weekday trains (Tuesday to Thursday). The approximate factors were: All trains: 0.96 Intermodal Trains: 0.98

2. Through trains were assumed to be split 50 percent eastbound and 50 percent westbound over the course of the day.

3. The analysis assumed two tracks at each at-grade crossing. Currently, four of the nine roadways with major at-grade crossings are double-track crossings. The remaining roadways have two separate single-track crossings that, for analysis purposes, have an effect similar to one double-track crossing.[3] In addition, in the Gardner IMF scenarios, the major single-track crossings would either be eliminated (183rd Street, Four Corners Road, and 191st Street) or consolidated into double-track crossings (Waverly Road and 199th Street).

4. The roadway saturation flow was assumed to be 1,600 vehicles per hour per lane.

5. Train flows were assumed to be uniform. Therefore, average weekday trains divided by 24 hours would provide the average expected number of trains during any one hour.

6. Through trains were assumed to occasionally pass each other, thereby reducing the total amount of blocked time due to all trains, but increasing the length of time for some of the individual blockages. A probability was assigned to this occurrence in keeping with the expected number of trains per hour. The resulting probability was low and had a minimal effect on the analysis results.

Key Equations

Average Blocked Time for a Single-Train Crossing Event
Average blocked time for a single train crossing event was calculated based on the length of the train and the average speed of the train plus warning and gate time. The warning and gate time was conservatively assumed to be 40 seconds total for each crossing. This included the time before the train arrived and after the train departed from the crossing (e.g. flashing light warning time, gate closing time, gate down time before and after the train, and gate opening time). The 40 seconds was added to the estimated time that the train was physically across the roadway to give a total "blocked time" estimate.

$$BT = TL / TS + 40 \text{ sec}$$

BT = Average Blocked Time (sec)
TL = Average Train Length (feet)
TS = Average Train Speed (feet/sec)
40 seconds is the additional warning / gate time

Average Blocked Time for a Two Train Crossing Event
In the fairly rare event of two trains passing each other across an at-grade crossing, the total blocked time will increase above that for a single train event. The minimum blockage would occur if the fronts of both trains arrived at the crossing at the same time. In this situation, the blockage would be the same as for a single train event (assuming both trains were the same length and were traveling the same speed). The maximum blockage would occur when a second train arrived just as the first train finished crossing. In this case the blockage would be approximately equal to two single-event blockages. Therefore, the average blocked time for a two train event would be midway between these two extremes. Average blocked time for a two-train event was calculated as follows:

$$BT_{12} = (MAX(BT_1, BT_2) + BT_1 + BT_2) / 2$$

BT_{12} = Average blocked time for two trains passing each other at an at-grade crossing (sec)
BT_1 = Average blocked time for train crossing in the eastbound direction (sec)
BT_2 = Average blocked time for train crossing in the westbound direction (sec)

[3] 191st Street has only one single-track crossing, but the southern single-track crossing on Four Corners Road also affects through traffic on 191st Street so it was treated in the same manner as all of the other roadways.

Total Average Blocked Time Per Hour for a Crossing (min/hr)

The total average blocked time per hour presents the average cumulative number of minutes each hour that the at-grade crossing is blocked to highway vehicles. It is the sum of the blocked times for each of the possible train crossing events (single eastbound train, single westbound train, simultaneous eastbound and westbound trains) multiplied by the average hourly frequency of each event.

$BT_{tot} = ((BT_1 \times T_1) + (BT_2 \times T_2) + (BT_{12} \times T_{12})) / 60$ *sec/min*

BT_1 = *Average blocked time for train crossing in the eastbound direction (sec)*
BT_2 = *Average blocked time for train crossing in the westbound direction (sec)*
BT_{12} = *Average blocked time for simultaneous train crossings in the EB and WB directions (sec)*
T_1 = *Expected train crossings in the eastbound direction (trains / hour)*
T_2 = *Expected train crossings in the westbound direction (trains / hour)*
T_{12} = *Expected simultaneous train crossings in the eastbound and westbound direction (events / hour)*

Expected Train Crossing Probabilities and Expected Train Crossings Per Hour
As outlined in the assumptions discussion, the train arrival patterns were assumed to be uniform in this analysis. The one complication introduced into this assumption was that through trains in opposite directions could arrive at the same time. To estimate the number of train crossing events, probabilities were first assigned to each.

Probability of Two Trains Passing the Crossing at the Same Time
$P_{12} = (F_1 \times BT_1 / (3600*24)) \times (F_2 \times BT_2 / (3600*24))$

F_1 = *Frequency of eastbound trains (trains per day)*
F_2 = *Frequency of westbound trains (trains per day)*
BT_1 = *average blocked time for train crossing in the eastbound direction (sec)*
BT_2 = *average blocked time for train crossing in the westbound direction (sec)*

Probability of Only One Train Passing the Crossing (One Direction)
$P_1 = (F_1 \times BT_1 / (3600*24)) \times (1 - (F_2 \times BT_2 / (3600*24)))$

F_1 = *Frequency of eastbound trains (trains per day)*
F_2 = *Frequency of westbound trains (trains per day)*
BT_1 = *average blocked time for train crossing in the eastbound direction (sec)*
BT_2 = *average blocked time for train crossing in the westbound direction (sec)*

Based on the above probabilities it was possible to calculate the expected number of crossing events per hour for use in further analysis.

Expected Two-Train Crossing Events Per Hour
$T_{12} = (T_{U1} + T_{U1}) \times (P_{12} / (P_1 + P_2 + (P_{12} \times 2))) / 2$

T_{U1} = *Unadjusted trains per hour (total eastbound trains / 24 hours)*
T_{U2} = *Unadjusted trains per hour (total westbound trains / 24 hours)*
P_{12} = *Probability of two trains passing the crossing at the same time*
P_1 = *Probability of eastbound train passing the crossing*
P_2 = *Probability of westbound train passing the crossing*

Expected One-Train Crossing Events Per Hour (One Direction)
$T_1 = (F_1 / 24) – T_{12}$

F_1 = *Frequency of eastbound trains (trains per day)*
T_{12} = *Expected Two-Train Crossing Events Per Hour*

Vehicles Queued During a Blockage (not including queue clearance time)
The number of highway vehicles that will queue in one direction during a crossing event can be determined based on the length of the blockage and the number of vehicles arriving on the highway in that direction. For example:

$$Q_{1w} = BT_1 \times (V_w / 3600)$$

BT_1 = *average blocked time for train crossing in the eastbound direction (sec)*
V_w = *Highway volume in the westbound or northbound direction at the crossing*

Queue Clearance Time
The time to clear the queue in one direction is related to the length of the queue, the number of arriving vehicles, the saturation flow, and the number of lanes. For example:

$$QC_{1w} = Q_{1w} / ((N_w \times S / 3600) - (V_w / 3600))$$

Q_{1w} = *Vehicles queued in the westbound or northbound direction during* BT_1
N_w = *Number of westbound or northbound lanes on highway*
S = *Saturation flow (veh/lane/hr)*
V_w = *Highway volume in the westbound or northbound direction at the crossing (veh/hr)*

Maximum Vehicles In Queue
The maximum vehicles in a queue as a result of a crossing being blocked are a function of the blocked time, the highway volume, and the queue clearance time. For example:

$$Q_{1wmax} = (BT_1 + QC_{1w}) \times (V_w / 3600)$$

BT_1 = *average blocked time for train crossing in the eastbound direction (sec)*
QC_{1w} = *time to clear queue in the westbound or northbound direction after* BT_1
V_w = *Highway volume in the westbound or northbound direction at the crossing (veh/hr)*

Vehicles Queued or Delayed Per Hour
The approximate number of vehicles queued (or delayed) per hour is equal to the total vehicles queued per crossing event multiplied by the probability of the crossing event.

$$Q_{1tot} = T_1 \times (Q_{1wmax} + Q_{1emax})$$

Q_{1wmax} = *Maximum vehicles in queue (eastbound train westbound or northbound vehicles)*
Q_{1emax} = *Maximum vehicles in queue (eastbound train eastbound or southbound vehicles)*
T_1 = *Expected one-train crossing events per hour (eastbound direction)*

To estimate the total vehicles queued (or delayed) from all trains at a crossing ($\mathbf{Q_{tot}}$), three values must be summed: eastbound trains, westbound trains, and simultaneous trains.

$$Q_{tot} = Q_{1tot} + Q_{2tot} + Q_{12tot}$$

Vehicular Crossing Delay Per Train (sec)
The delay to vehicles per train crossing event is related to the length of the blockage, the volume of vehicles, the number of lanes, and saturation flow according to the following equation:

$$D_{1w} = (N_w \times S \times V_w \times (BT_1 / 3600)^2) / (2 \times (N_w \times S - V_w)) \times 3600$$

N_w = *Number of westbound or northbound lanes on highway*
S = *Saturation flow (veh/lane/hr)*
V_w = *Highway volume in the westbound or northbound direction at the crossing (veh/hr)*
BT_1 = *average blocked time for train crossing in the eastbound direction (sec)*

Expected Total Delay
The expected total delay is the expected number of crossing events multiplied by sum of the total vehicular crossing delay per train. For example:

$D_{1tot} = T_1 \times (D_{1w} + D_{1e})$

T_1 = *Expected one-train crossing events per hour (eastbound direction)*
D_{1w} = *Vehicular crossing delay per train for westbound or northbound vehicles (sec)*
D_{1e} = *Vehicular crossing delay per train for eastbound or southbound vehicles (sec)*

To estimate the total vehicle delay from all trains at a crossing ($\mathbf{D_{tot}}$), three values must be summed: eastbound trains, westbound trains, and simultaneous trains.

$D_{tot} = D_{1tot} + D_{2tot} + D_{12tot}$

Average Delay Per Vehicle
The average delay per vehicle is based on the total expected delay and the number of vehicles crossing at that location.

$D_{ave} = D_{tot} / (V_w + V_e)$

Average Blocked Time Per Train (sec)
The average blocked time per train is related to the total blocked time at a crossing divided by the number of trains at the crossing.

$BT_{ave} = (BT_{tot} \times 60 \text{ sec/min}) / ((F_1 + F_2) / 24 \text{ hours/day})$

BT_{tot} = *Total Average Blocked Time Per Hour for a Crossing (min/hr)*
F_1 = *Frequency of eastbound trains (trains per day)*
F_2 = *Frequency of westbound trains (trains per day)*

Average Delay Per Delayed Vehicle
The average delay per delayed vehicle is related to the total delay at the crossing divided by the number of queued (or delayed) vehicles.

$D_d = D_{tot} / Q_{tot}$

D_{tot} = *Total expected delay*
Q_{tot} = *Total vehicles queued or delayed per hour*

Agency or Company: HDR Inc.
Date Performed: 3/18/2008 10:15:14 AM
Analysis Time Period: AM
Freeway/Direction: I-35 Northbound
From/To: Edgerton Road to Sunflower Road
Jurisdiction:
Analysis Year: 2008
Description: NEPA Traffic Study

_________Flow Inputs and Adjustments_________

Volume, V	1130	veh/h
Peak-hour factor, PHF	0.90	
Peak 15-min volume, v15	314	v
Trucks and buses	9	%
Recreational vehicles	0	%
Terrain type:	Level	
Grade	0.00	%
Segment length	0.00	mi
Trucks and buses PCE, ET	1.5	
Recreational vehicle PCE, ER	1.2	
Heavy vehicle adjustment, fHV	0.957	
Driver population factor, fp	1.00	
Flow rate, vp	656	pc/h/ln

_________Speed Inputs and Adjustments_________

Lane width	12.0	ft
Right-shoulder lateral clearance	6.0	ft
Interchange density	0.50	interchange/mi
Number of lanes, N	2	
Free-flow speed:	Measured	
FFS or BFFS	70.0	mi/h
Lane width adjustment, fLW	0.0	mi/h
Lateral clearance adjustment, fLC	0.0	mi/h
Interchange density adjustment, fID	0.0	mi/h
Number of lanes adjustment, fN	0.0	mi/h
Free-flow speed, FFS	70.0	mi/h
	Rural Freeway	

_________LOS and Performance Measures_________

Flow rate, vp	656	pc/h/ln
Free-flow speed, FFS	70.0	mi/h
Average passenger-car speed, S	70.0	mi/h
Number of lanes, N	2	
Density, D	9.4	pc/mi/ln
Level of service, LOS	A	

Overall results are not computed when free-flow speed is less than 55 mph.

Merge Analysis

Analyst:	Trishul Palekar
Agency/Co.:	HDR Inc.
Date performed:	3/18/2008 11:13:41 AM
Analysis time period:	AM
Freeway/Dir of Travel:	I-35 Southbound
Junction:	13 Sunflower Entr
Jurisdiction:	KDOT
Analysis Year:	2008

Description: NEPA Traffic Study

Freeway Data

Type of analysis	Merge	
Number of lanes in freeway	2	
Free-flow speed on freeway	70.0	mph
Volume on freeway	465	vph

On Ramp Data

Side of freeway	Right	
Number of lanes in ramp	1	
Free-flow speed on ramp	35.0	mph
Volume on ramp	4	vph
Length of first accel/decel lane	800	ft
Length of second accel/decel lane		ft

Adjacent Ramp Data (if one exists)

Does adjacent ramp exist?	No	
Volume on adjacent Ramp		vph
Position of adjacent Ramp		
Type of adjacent Ramp		
Distance to adjacent Ramp		ft

Conversion to pc/h Under Base Conditions

Junction Components	Freeway	Ramp	Adjacent Ramp	
Volume, V (vph)	465	4		vph
Peak-hour factor, PHF	0.90	0.90		
Peak 15-min volume, v15	129	1		v
Trucks and buses	18	0		%
Recreational vehicles	0	0		%
Terrain type:	Level	Rolling		
Grade	%	%	%	
Length	mi	mi	mi	
Trucks and buses PCE, ET	1.5*	2.5		
Recreational vehicle PCE, ER	1.2*	2.0		
Heavy vehicle adjustment, fHV	0.917	1.000		
Driver population factor, fP	1.00	1.00		
Flow rate, vp	563	4		pcph

Estimation of V12 Merge Areas

L_{EQ} = (Equation 25-2 or 25-3)

P_{FM} = 1.000 Using Equation 0

$v_{12} = v_F (P_{FM})$ = 563 pc/h

Capacity Checks

	Actual	Maximum	LOS F?
v_{FO}	567	4800	No
v_{3} or v_{av34}	0 pc/h	(Equation 25-4 or 25-5)	
Is v_{3} or v_{av34} > 2700 pc/h?		No	
Is v_{3} or v_{av34} > 1.5 v_{12}/2		No	
If yes, v_{12A} =		(Equation 25-8)	

Flow Entering Merge Influence Area

	Actual	Max Desirable	Violation?
v_{12}	563	4400	No

!

Level of Service Determination (if not F)

Density, $D_R = 5.475 + 0.00734\, v_R + 0.0078\, v_{12} - 0.00627\, L_A$ = 4.9 pc/mi/ln

Level of service for ramp-freeway junction areas of influence A

Speed Estimation

Intermediate speed variable,	M_S = 0.272	
Space mean speed in ramp influence area,	S_R = 62.4	mph
Space mean speed in outer lanes,	S_0 = N/A	mph
Space mean speed for all vehicles,	S = 62.4	mph

_____Operational Analysis_____

Analyst: Trishul Palekar
Agency or Company: HDR Inc.
Date Performed: 3/20/2008 1:45:04 PM
Analysis Time Period: PM
Freeway/Direction: I-35 Southbound
From/To: US 56 to Gardner Road
Jurisdiction: KDOT
Analysis Year: 2010
Description: NEPA Traffic Study

_____Flow Inputs and Adjustments_____

Volume, V	2080	veh/h
Peak-hour factor, PHF	0.90	
Peak 15-min volume, v15	578	v
Trucks and buses	9	%
Recreational vehicles	0	%
Terrain type:	Level	
Grade	0.00	%
Segment length	0.00	mi
Trucks and buses PCE, ET	1.5	
Recreational vehicle PCE, ER	1.2	
Heavy vehicle adjustment, fHV	0.957	
Driver population factor, fp	1.00	
Flow rate, vp	1208	pc/h/ln

_____Speed Inputs and Adjustments_____

Lane width	12.0	ft
Right-shoulder lateral clearance	6.0	ft
Interchange density	0.50	interchange/mi
Number of lanes, N	2	
Free-flow speed:	Measured	
FFS or BFFS	70.0	mi/h
Lane width adjustment, fLW	0.0	mi/h
Lateral clearance adjustment, fLC	0.0	mi/h
Interchange density adjustment, fID	0.0	mi/h
Number of lanes adjustment, fN	0.0	mi/h
Free-flow speed, FFS	70.0	mi/h
	Rural Freeway	

_____LOS and Performance Measures_____

Flow rate, vp	1208	pc/h/ln
Free-flow speed, FFS	70.0	mi/h
Average passenger-car speed, S	70.0	mi/h
Number of lanes, N	2	
Density, D	17.3	pc/mi/ln

Is v_3 or v_{av34} > 1.5 v_{12} /2		No	
If yes, v_{12A} =		(Equation 25-18)	

Flow Entering Diverge Influence Area

	Actual	Max Desirable	Violation?
v_{12}	642	4600	No

!

Level of Service Determination (if not F)

Density, $D_R = 4.252 + 0.0086 v_{12} - 0.009 L_D$ = 2.6 pc/mi/ln

Level of service for ramp-freeway junction areas of influence A

Speed Estimation

Intermediate speed variable,	D_S = 0.433	
Space mean speed in ramp influence area,	S_R = 57.9	mph
Space mean speed in outer lanes,	S_0 = N/A	mph
Space mean speed for all vehicles,	S = 57.9	mph

Merge Analysis

Analyst: Tom Hiles
Agency/Co.: HDR Inc.
Date performed: 3/27/2008 10:25:01 AM
Analysis time period: PM
Freeway/Dir of Travel: I-35 Southbound
Junction: 13 Sunflower Entr
Jurisdiction: KDOT
Analysis Year: 2010
Description: NEPA Traffic Study

Freeway Data

Type of analysis	Merge	
Number of lanes in freeway	2	
Free-flow speed on freeway	70.0	mph
Volume on freeway	1350	vph

On Ramp Data

Side of freeway	Right	
Number of lanes in ramp	1	
Free-flow speed on ramp	35.0	mph
Volume on ramp	30	vph
Length of first accel/decel lane	800	ft
Length of second accel/decel lane		ft

Adjacent Ramp Data (if one exists)

Does adjacent ramp exist?	No	
Volume on adjacent Ramp		vph
Position of adjacent Ramp		
Type of adjacent Ramp		
Distance to adjacent Ramp		ft

Conversion to pc/h Under Base Conditions

Junction Components	Freeway	Ramp	Adjacent Ramp	
Volume, V (vph)	1350	30		vph
Peak-hour factor, PHF	0.90	0.90		
Peak 15-min volume, v15	375	8		v
Trucks and buses	11	7		%
Recreational vehicles	0	0		%
Terrain type:	Level	Rolling		
Grade	%	%	%	
Length	mi	mi	mi	
Trucks and buses PCE, ET	1.5*	2.5		
Recreational vehicle PCE, ER	1.2*	2.0		
Heavy vehicle adjustment, fHV	0.948	0.905		
Driver population factor, fP	1.00	1.00		
Flow rate, vp	1583	37		pcph

Estimation of V12 Merge Areas

L_{EQ} = (Equation 25-2 or 25-3)

P_{FM} = 1.000 Using Equation 0

$v_{12} = v_F (P_{FM})$ = 1583 pc/h

Capacity Checks

	Actual	Maximum	LOS F?
v_{FO}	1620	4800	No
v_{3} or v_{av34}	0 pc/h	(Equation 25-4 or 25-5)	
Is v_{3} or v_{av34} > 2700 pc/h?		No	
Is v_{3} or v_{av34} > 1.5 v_{12} /2		No	
If yes, v_{12A} =		(Equation 25-8)	

Flow Entering Merge Influence Area

	Actual	Max Desirable	Violation?
v_{12}	1583	4400	No

!

Level of Service Determination (if not F)

Density, $D = 5.475 + 0.00734 v_R + 0.0078 v_{12} - 0.00627 L_A$ = 13.1 pc/mi/ln

Level of service for ramp-freeway junction areas of influence B

Speed Estimation

Intermediate speed variable, M_S = 0.285

Space mean speed in ramp influence area, S_R = 62.0 mph

Space mean speed in outer lanes, S_0 = N/A mph

Space mean speed for all vehicles, S = 62.0 mph

Recreational vehicles	0	%
Terrain type:	Level	
Grade	0.00	%
Segment length	0.00	mi
Trucks and buses PCE, ET	1.5	
Recreational vehicle PCE, ER	1.2	
Heavy vehicle adjustment, fHV	0.939	
Driver population factor, fp	1.00	
Flow rate, vp	1136	pc/h/ln

_______Speed Inputs and Adjustments_______

Lane width	12.0	ft
Right-shoulder lateral clearance	6.0	ft
Interchange density	0.50	interchange/mi
Number of lanes, N	2	
Free-flow speed:	Measured	
FFS or BFFS	70.0	mi/h
Lane width adjustment, fLW	0.0	mi/h
Lateral clearance adjustment, fLC	0.0	mi/h
Interchange density adjustment, fID	0.0	mi/h
Number of lanes adjustment, fN	0.0	mi/h
